Kettering Park Site

ABSTRACT

A Phase I survey was conducted by Terrence Epperson in 1979 along the proposed dualization corridor of Maryland 214, Prince Georges County, Maryland. As a result of the survey, the Kettering Park Site (18PR174) was identified. In 1983, Maureen Kavanagh and Silas Hurry directed a Phase II testing program at Kettering Park. Phase II testing consisted of the excavation of systematic shovel tests and 11 one meter-square test units. At the conclusion of the testing program, it was determined that the prehistoric occupation of the Kettering Park Site spanned from the Early Archaic to the Late Woodland. The vertical distribution of artifacts indicated the presence of a Late Archaic/Early Woodland transitional component contained in subplowzone deposits, or the A2 horizon. Based on these results, the site was considered to be eligible for inclusion in the National Register of Historic Places under Criterion D and Phase III data recovery excavations were proposed. A research design was developed to address issues relating to prehistoric settlement and technology. Kavanagh and Hurry conducted Phase III excavations at the site in 1985 to mitigate any adverse effects to the site which would be caused by construction activities. A 10% sample was obtained through the excavation of 13 two-meter square units. In 1993, Engineering-Science Inc., was contracted with the State Highway Administration to synthesize the field and laboratory results and to write the combined Phase II-III report.

Synthesis and analysis of the data indicates that the Kettering Park Site consists of varying combinations of Archaic and Woodland lithic and ceramic artifacts in plowzone and stratified contexts. Based on the density of ceramics and temporally diagnostic projectile points, the Late Archaic and the Early Woodland periods are considered the most significant occupation of the site. Diagnostic artifacts of the Early Woodland period included the largest sample of Accokeek ceramics recovered from any site along the Patuxent drainage. Analysis of the horizontal distribution of artifacts identified potential activity areas -- in particular, lithic manufacturing areas. The goals of the data recovery program were implemented and met, mitigating the adverse effect of construction on the site. Since concluding the field work, the Maryland State Highway Administration completed construction of the dualized road segment.

ACKNOWLEDGEMENTS

The Maryland State Highway Administration supported the field, laboratory, and report writing stages of the Kettering Park Site investigations. The Kettering Park Site investigations would not have been completed without the contributions of many individuals. The Phase II and III field projects were directed by Maureen Kavanagh and Silas Hurry. The field crew for the Phase II testing program included Edward Chaney, Katherine Dinnel, and Spencer Geasey. The Phase III excavation crew members were Stephanie Crockett, Katherine Dinnel, Timothy Doyle, Elizabeth Leigh Hutchenson, William Huser, Janet Gillis, Alison Helms, and Timothy Sara.

The artifacts recovered during the Phase II investigations at the Kettering Park Site were processed by Edward Chaney and Katherine Dinnel. After the processing of the Phase II artifacts was completed, members of the former Maryland Division of Archeology developed a detailed computer cataloguing system. This system was used by Carol Ebright and William Huser to record the Phase III artifacts. Carol Ebright and Maureen Kavanagh re-catalogued the Phase II artifacts utilizing the computer system in order to make the databases for these two phases of excavation more consistent. The original ceramic analysis for Phase II artifacts was completed by Katherine Dinnel. Subsequently, Maureen Kavanagh expanded this work and these results were incorporated into the Phase II and Phase III ceramic sections of this report. Carol Ebright completed the preliminary lithic analysis.

Engineering-Science’s compilation of data and report synthesis could not have been completed without the generous assistance and contributions of Carol Ebright. Maureen Kavanagh and Silas Hurry provided valuable comments on an earlier draft report. A list of key individuals involved in the project appears in Appendix A.
I. INTRODUCTION

The Maryland State Highway Administration dualized Maryland 214 (Central Avenue) in Prince Georges County, Maryland. The construction upgraded the former two-lane road and added another two-lane thoroughfare south of the right-of-way. The upgraded road corridor measured 5.4 miles in length, stretching from Interstate 495 east to Hall. The construction also realigned the Interstate 495 - Maryland 202 segment slightly to the north, and upgraded the Maryland 214 - Maryland 202 intersection at Largo.

In 1979, Terrence Epperson directed a Phase I survey of the proposed Maryland 214 project corridor. The survey was restricted to a 300-foot-wide easement along the existing road and a 300-foot-wide area surrounding the Maryland 214 - Maryland 202 intersection at Largo. The goal of the Phase I survey was to locate and identify any archaeological sites located in the project area. The Kettering Park Site (18PR174) was discovered during the survey. The site was situated in the Riverine Patuxent Drainage Research Unit at the confluence of the Western and Northeastern Branches of the Patuxent River (Figures 1 and 2). Phase II investigations were proposed because of the site's location in the construction area and its potential eligibility for inclusion in the National Register of Historic Places (Epperson 1979:8).

Maureen Kavanagh, M.A., and Silas Hurry, B.A., directed Phase II excavations in April and May 1983. The objectives of the Phase II testing program were to determine site integrity, site boundaries, cultural affiliation, and to evaluate the Kettering Park Site's eligibility for inclusion in the National Register of Historic Places. Upon completion of the Phase II investigations, more intensive excavations were recommended because observations and preliminary the data analysis suggested that intact Early Woodland deposits were present at the site. Although a draft report of the Phase II work was prepared by Maureen Kavanagh, it was not completed due to the imminence of Phase III excavations.

The Maryland State Highway Administration and the Maryland Historical Trust agreed that the Kettering Park Site was eligible for listing on the National Register of Historic Places for its ability to yield information about prehistory. The goal of the Phase III excavations was to mitigate any adverse effects to the site caused by construction activities. An in-depth research design was developed to direct the site excavations. Phase III excavations, directed by Maureen Kavanagh and Silas Hurry, were carried out in November and December 1985.
Kettering Park Site

Figure 1
 Maryland Research Unit Map
In 1993, the Cultural Resources Department of Engineering-Science, Inc., was contracted by the Maryland State Highway Administration to complete the artifact analysis and to write a combined Phase II-III report. All artifacts, dBase III+ files, preliminary reports, and field notes were provided to assist in preparing this report. However, the report was written without the benefit of the Phase II and III field photographs. This report synthesizes the Phase II and III field and laboratory results. It also contains analysis of all lithic and ceramic artifacts recovered at the Kettering Park Site.

The archaeological investigations were performed in compliance with the National Historic Preservation Act of 1966, as amended; the National Environmental Policy Act of 1969, as amended; the Department of Transportation Act of 1966, as amended; the "Consultant Specifications for Archaeological Services" of the Maryland State Highway Administration; the Maryland Historic Trust Act of 1985, as amended; and the "Guidelines for Archeological Investigations in Maryland" (McNamara 1981).
II. ENVIRONMENTAL BACKGROUND

Setting

The Kettering Park Site is located on a low alluvial terrace situated on the south side of Maryland 214, between Largo and Kolbes Corner (Figure 2). The site is at the confluence of the Western and Northeastern Branches of the Patuxent River, about 22 m above sea level. The area lies within the Western Shore Region of the Atlantic Coastal Plain physiographic province. The Coastal Plain physiographic province is marked by gently rolling topography cut by broad, meandering water courses.

The Maryland 214 corridor crossed three tributaries of the Patuxent River. These tributaries are a second-order tributary called the Southwest Branch, and two third-order tributaries known as the Western Branch and the Northern Branch. The construction along Interstate 495 and the Interstate 495 - Maryland 202 interchange displaced the Southwest Branch tributary. Channelization of the Northern and Western Branch streams occurred between 1965 and 1979 (Kavanagh n.d.). Proximity to these branches has contributed to stream sediment deposition, erosion, and flooding along the site edges. The study area also has been impacted by both urban and agricultural developments.

Climate

The region’s climate is described as continental, being temperate and at times humid. Weather systems generally move through the area from the northwest in winter and the southeast in summer. Modern temperatures range from an average high of 87.8 degrees Fahrenheit in July to an average low of 24.2 degrees Fahrenheit in February, with a year-round mean of 55 degrees. Average annual precipitation totals approximately 45 inches, with the highest amounts falling from May through August. Of the total precipitation, an average of 1.9 to 2.0 inches falls in the form of snow (with one inch of snow calculated as 0.10 inches of precipitation). Both temperature ranges and rainfall are slightly greater than those in adjacent areas on the Coastal Plain, where the ameliorating effects of the Chesapeake Bay and Atlantic Ocean are more directly felt. In winter, higher humidity and precipitation often result from northeasterly winds off the Atlantic, while the Appalachians to the west help to moderate the coldest temperatures (Mack 1966; Kirby et al. 1967).
6 Kettering Park Site

Flora and Fauna

Prior to European colonization, most of the area that now comprises Prince Georges County was forested, containing primary stands of hardwoods, such as red and white oak, sweet gum, and yellow-poplar. Virginia pine has become a subdominant species in cleared regions. An often thick understory lies at the base of the secondary hardwood stands, particularly in wet or marshy areas, and includes Virginia creeper, myrtle, sumac, and the ubiquitous greenbriar and poison ivy. A variety of grasses may also flourish in portions of cleared areas.

Deer, whose breaks are evident in clearings across the region, are the largest mammals remaining in the area, and are drawn particularly to woodland locales, which also attract raccoon, grey and red squirrel, turkey, ruffed grouse, woodcock, and thrush. Open areas may attract rabbit, woodchuck, red fox, quail, dove, meadowlark, and pheasant. A variety of small mammals, birds, and reptile species also inhabit the stream margins and overlying terraces. Raccoon, muskrat, duck, geese, rail, and heron are found in wetland areas. Though larger migratory fowl are generally confined to tidal wetlands to the south along the Anacostia and upper Potomac Rivers, geese can be observed in non-tidal wetland areas. Small freshwater fish inhabit larger order streams. Anadromous and semi-anadromous species have been observed in the Northeast Branch just below the study area (Lipson et al. 1979). Siltation within the tributaries, resulting from historic land clearing for agricultural and industrial use, has probably limited the upstream extent of these spawning areas, which may in the past have extended up smaller streams such as Paint Branch, Indian Creek, and Beaverdam Creek.
III. PREHISTORIC ENVIRONMENT, OCCUPATION, AND LAND USE

The prehistory of Prince Georges County and the Middle Atlantic region in general is traditionally divided into three major cultural periods: the Paleo-Indian (ca. 10,000 B.C. - 7500 B.C.), the Archaic (ca. 7500 B.C. - 1000 B.C.), and the Woodland (ca. 1000 B.C. - A.D. 1600). These periods are used as a taxonomic device, a framework within which to examine the cultural processes operating throughout prehistory. The evidence for their demarcation is derived from transformations in technology, or material culture as seen through the study of stone and ceramic artifacts. Archaeology operates, by definition, from a materialistic perspective, focusing on the study of technology. Many of the technology products tend to be quite durable and, by surviving to the present, these materials become the most directly observable aspects of past cultures available to the analyst. Technology is seen as a means of adaptation to the surrounding environment. Thus, a study of the physical environment of a region and the alterations it has undergone during periods of human occupation may furnish insight into the nature and availability of habitats suitable to prehistoric populations, and thereby provide a background for the description of cultural change as seen through artifact variation.

_Paleo-Indian Period_

The record of human habitation in the Middle Atlantic region begins some 12,000 years ago, near the end of the cool and relatively wet Late Wisconsin Glacial period, at a time when large amounts of water remained trapped in the Laurentian ice sheet not far to the north. The edge of the ice was preceded by a narrow, 60- to 100-km band of open tundra, while most of the Coastal Plain to the south was dominated by jack pine forest with a subdominant component of spruce and fir (Delcourt and Delcourt 1981). Global sea levels were considerably lower than at present, and so the Potomac and Anacostia Rivers to the west were as yet freshwater river valleys.

By this period, environmental shifts were in progress that greatly enhanced subsistence resource potential for the prehistoric inhabitants of the region. With the retreat of the northern glaciers, the entire Middle Atlantic was undergoing a fairly rapid warming trend (Carbone 1986), which was directly reflected in the replacement of northern plant and animal species by southern types. A mixed conifer/northern hardwood forest interspersed with open grassland expanded northward from the Carolinas, for example, gradually replacing existing jack pine/spruce forests (Delcourt and Delcourt 1981). Like much of the region in general, northern Prince Georges County was characterized by a relatively complex set of overlapping microenvironmental zones, providing a variety of subsistence resources for prehistoric
8 *Kettering Park Site*

populations. The large Pleistocene-era grazing and browsing animals, associated with Folsom and Clovis cultures in the West, were by this point mostly gone from the Middle Atlantic region. Smaller herds would have been present within forested areas in the Middle Atlantic, and the woods and transitional zones would have supported a much wider range of floral and small faunal species than the western savannas (Wesler *et al.* 1981). Consequently, big game hunting may have been a somewhat less important part of the subsistence round, augmented substantially by exploiting a seasonal variety of other plant and animal resources (Humphrey and Chambers 1977; Johnson 1986; Custer 1989).

Archaeological sites dating to this period are usually identified by the presence of fluted stone projectile points, often made of high quality, cryptocrystalline lithic material such as chert or jasper. These points, used as spear tips, are relatively rare throughout the Middle Atlantic. The points are usually found alone, without other artifacts nearby, and it is unclear whether they represent camp sites or hunting forays.

The region’s most intensively studied Paleo-Indian sites are situated in the Shenandoah Valley of Virginia. Excavation of these sites has indicated that Paleo-Indian base camps tend to be situated in areas of high resource diversity, particularly near sources of cryptocrystalline stone (Gardner 1974, 1989). Other smaller, more temporary camp sites were situated nearby to serve a variety of purposes, and even more ephemeral hunting camps were often situated further still from the base camp location. A similar pattern has been noted for areas where cryptocrystalline stone is available in northern Delaware (Custer and DeSantis 1985). In central Delaware, where high quality lithic material is not available, Custer and DeSantis (1985) have suggested that base camps tended to be associated with topographic features rather than with lithic resource concentrations; sites were most often located on well-drained ridges in areas of maximum habitat overlap (Custer and DeSantis 1985). While cryptocrystalline materials appears to be preferred for the production of Paleo-Indian projectiles, there are examples, such as the Higgins site, in Anne Arundel County, which contains Clovis points made from quartz (Ebright 1992).

Relatively few Paleo-Indian sites have been reported throughout the Middle Atlantic. It is probable that many were located on the continental shelf and are now submerged by the rise in sea level which accompanied the melting of the polar ice sheets at the end of the Wisconsin glaciation, ca. 14,000 B.P. (Kraft and John 1978). Others probably lay along the banks of now drowned rivers such as the Potomac and Anacostia. Fluted points have been reported from locations to the west in Fairfax County, Virginia (Johnson 1986) and to the east from nearby sections of the Maryland Coastal Plain (Steponaitis 1980; Brennan 1982; Wanser 1982; Ebright
1992). Though many are in fact from unprovenienced collections, a sample with good context was reported at the Higgins site in Anne Arundel County (Ebright 1992).

**Archaic Period**

The Archaic Period extended from ca. 7500 B.C. to 1000 B.C. It was characterized by response to the emergence of the so-called full Holocene environment, an environment increasingly like that of the present (Joyce 1988). Seasonal population migration, hunting and gathering subsistence, and small-scale egalitarian social systems were typical of the period. Major subperiods are recognized within the Archaic Period, referred to as Early, Middle, and Late.

One of the most important environmental changes affecting prehistoric populations throughout the Middle Atlantic region during the Archaic Period was the gradual rise in sea level accompanying the retreat of the continental ice sheets. Known as the Holocene marine transgression, the rise in sea level produced widespread lowland flooding, which extended up many Pleistocene river valleys, giving rise to the term "drowned" river valley. Among the effects of inundation were a marked rise in local water tables, an increase in shoreline complexity associated with estuary development, and the consequent increase in floral and faunal resources in newly formed marsh or wetland areas (Potter 1982).

The rate of sea level rise, and thus of estuary formation, was not constant throughout the period. Sea level curves have been constructed for various locations along the eastern seaboard; they show an interval of fairly rapid increase in the rate of sea level rise from 10,000 B.C. to 6000 B.C., followed by a marked decrease (Stuiver and Daddario 1963). Inundation of the Susquehanna River system, which resulted in the formation of the Chesapeake Bay, began with the initial rise in sea level between 14,500 and 14,000 B.C. By 9500-9000 B.C., marine transgression had reached the mouth of the Potomac, below what is today Point Lookout (Wanser 1982). The Bay appears to have reached something resembling its present configuration by around 3000 B.C., and largely stabilized at that point, as the rate of inland inundation decreased drastically, allowing the maturation of estuary areas (Gardner 1979; Delcourt and Delcourt 1981).

In practice, shoreline reconstructions for specific areas may vary markedly from global or pan-regional models. Local reconstructions must account for local conditions, such as sedimentation rates and regional tectonic movement -- land has risen recently in many portions
Kettering Park Site

of the Middle Atlantic, for example (Froomer 1980). The Anacostia River, at the upper end of the Potomac estuary basin, would have been among the last tributaries to become inundated. Though extensive studies have not been carried out along the Anacostia, core samples from two locations suggest that flooding began there between 7000 and 5000 B.C. (National Preservation Institute 1983).

Early Archaic

Most archaeologists agree that there is some continuity between the Paleo-Indian and the Early Archaic Periods (Gardner 1974; Custer 1989). While there is evidence for an increase in the number of sites, the Early Archaic inhabitants of the area, like their predecessors, probably exhibited high mobility and enjoyed a varied subsistence base. Intensified foraging may be assumed from the more transitory use of resource areas, suggested by the presence of smaller sites. The pollen record indicates that forests of the Middle Atlantic were oak-dominated by 7000 B.C., but also contained significant populations of hemlock, maple, birch, and pine, with spruce still evident at higher elevations (Joyce 1988).

The Early Archaic Period (ca. 7500 B.C. - 6500 B.C.) is marked by the introduction of several new projectile point styles. Among the cultural diagnostics of this period are the corner-notched, serrated Palmer and Kirk points; and the slightly later Kirk-stemmed types. A change in preference from cryptocrystalline to non-cryptocrystalline lithic materials appears to have become significant in portions of the Coastal Plain during the middle portion of the Early Archaic. Custer (1986) has noted a markedly greater occurrence of quartz and quartzite, for example, in Kirk-stemmed points than in the earlier types, which were largely manufactured of chert or jasper, this beginning about 7500 B.C. in Delmarva. Use of non-cryptocrystalline materials continued to grow significantly throughout the rest of the Early Archaic, to approximately 6000 B.C. Custer further notes that the change occurred after the switch from fluting to notching as a base or hafting element feature. Thus he associates the change in raw material selection with the onset of the "full Holocene environment," and not with morphological change. Doubtless the interplay of several factors -- population mobility, specific resource focus, lithic resource access, and hunting strategy among them -- was involved in the variation in lithic choice. Nonetheless, stability in the pattern of resource exploitation from the Paleo-Indian to the Early Archaic Period appears to have been the general rule.

Middle Archaic

By the Middle Archaic Period (ca. 6500 - 2500 B.C.), local populations were exploiting the new floral and faunal resources brought by the transformation of the mixed pine-oak forest
to a temperate oak-hemlock deciduous forest, beginning around 6,000 B.C. (Ritchie 1979). At this time also, a 1,000-year period of relative dryness was coming to a close (Joyce 1988). Pollen profiles from the Middle Archaic Period indicate the change in forest elements in the Middle Atlantic. Hemlock abruptly declined about 5000 B.C., and hickory continued to migrate into the area (Joyce 1988). Large marshes and swamps resulting from the ongoing inundation of coastal waterways became an important focus of occupation during the period, with seasonally specialized, transient procurement stations functioning as support facilities for estuarine base camps (Gardner 1979; Custer 1986).

The Middle Archaic artifact assemblage includes projectile point forms such as a transitional bifurcate type, the stemmed Stanly or Neville, and early long- or broad-bladed forms such as Guilford and Morrow Mountain. Later, the side-notched Halifax point (Coe 1964; Johnson 1986) is quite common in the area and this type is predominantly made of quartz. The tool kit was further marked by the appearance of ground stone tools.

_Late Archaic_

The succeeding Late Archaic Period (ca. 2500 B.C. - 1000 B.C.) was characterized by the prevalence of the oak-hickory forest environment. The rate of sea level rise slowed, allowing for the formation of riverine and estuarine environments stable enough to support significant populations of shellfish and anadromous fish in larger streams (Custer 1984; Gardner 1979). Sturgeon runs at the upper end of the Potomac were described by the earliest European explorers (Fleet in Neill 1876), and runs of American shad, white perch, herring, and alewife are recorded historically along tributaries of the Potomac and Anacostia above the fall line (Lippson _et al._ 1979). It is speculated that the focus of settlement shifted during the Late Archaic Period to riverine and estuarine locales to take advantage of increasingly predictable fish and shellfish resources.

For the Late Archaic Period, a marked increase in the number of sites is observed, suggesting both an overall population increase (Turner 1978) and movement into new environmental zones. Some sites in the riverine and estuarine areas tend to be larger and more complex than any occupied during previous periods, thereby indicating a trend toward sedentism and organized resource procurement strategies (Johnson 1986). Gardner (1982) maintains that, in the fall line region, large Late Archaic spring/summer base camps existed where large numbers of anadromous fish could be harvested, while smaller fall/winter base camps were situated along inland streams. Transient camps were located in a variety of environments offering additional support to the large and small base camp occupations.
12 Kettering Park Site

Cultural diagnostics of this period included steatite vessels and several types of broad-bladed points -- the Savannah River and Susquehanna broadspear -- found mainly in the Piedmont. Possibly serving as knives, these broader points may have been designed in part to exploit the new riverine resources. In many areas, particularly in the Piedmont to the west and north of the study area, rhyolite was the preferred lithic material for the manufacture of broad-bladed points, which are often found in association with vessels carved from steatite (Witthoft 1953; Ritchie 1965).

Woodland Period

Around 1000 B.C., techniques for the manufacture of pottery were introduced across the region. This innovation defines the beginning of the Woodland Period, which, like the Archaic, is traditionally divided into Early, Middle, and Late sub-periods.

Correlations between projectile point types and ceramic types are not well established for many portions of the Woodland in the Middle Atlantic: ceramics, which tend to have the more discretely defined time ranges in these later periods, have become the primary temporal indices. For example, some broad-bladed fishtail projectile point forms, characteristic of the end of the Late Archaic, have been associated with Early Woodland ceramics in the Chesapeake Bay area and the Upper Delaware Valley (Kinsey 1972; Wright 1973; Wesler 1983), and at a Woodland period fishing site in Washington, D.C. (McNutt and Gardner n.d.). There is also evidence that smaller side-notched points and the slightly thinner Potts (Winfree 1967; Johnson 1986) were associated with Early Woodland ceramics, as was the short-stemmed Calvert point (Stephenson and Ferguson 1963; Waselkov 1982).

Early Woodland

The earliest known ceramic in the area, used from about 1200 B.C. to 800 B.C., is a steatite-tempered variety referred to as Marcey Creek ware after its type site on the Potomac River in Arlington County, Virginia (Manson 1948). Its distribution range encompassed most of the Potomac River basin north of the James River and spread westward into the lower Piedmont (Egloff and Potter 1982). A radiocarbon date of 950 ± 95 B.C. was obtained from western Maryland for Marcey Creek pottery (Boyce and Frye 1986; Waselkov 1982). A subsequent diagnostic ceramic type of the Early Woodland Period is the sand and grit-tempered Accokeek ware in use from about 800 B.C. to 300 B.C.
Environmental stabilization in the Early Woodland Period (ca. 1000 B.C. - 500 B.C.) is evidenced by the lack of change in forest components in the region. These cores indicate the predominance of oak, hickory, and pine in the latter portion of the Archaic, around 3400 B.C. In general, environmental conditions remained the same to the present (Joyce 1988), except for relatively minor fluctuations such as the somewhat cooler and wetter sub-Atlantic period, ca. 2500 B.C. (Carbone 1986). A recent increase in pine, along with grasses and other non-arboreal species, reflects the extent of historic land clearing.

In general, the Late Archaic lifestyle continued into the Early Woodland Period. While the deliberate and intensive foraging strategies of the preceding period appear to have remained unchanged, there is some evidence for an increase in sedentism as the inhabitants of the area became more efficient in exploiting available resources. Gardner (1982) has postulated that, rather than breaking up into small base camps in interior freshwater settings, occupants of the large spring/summer base camps in anadromous fishing zones regrouped in the fall and winter near the freshwater/saltwater transition to take advantage of the abundant shellfish resources there.

Middle Woodland

Subsistence practices during the Middle Woodland Period (ca. 500 B.C. - A.D. 900) remained similar to that of the preceding Early Woodland, with a reliance on hunting, gathering, and fishing. There is some evidence for a shift in the locations of semi-sedentary base camps from small creek floodplains to large river floodplains, a shift that may have provided a basis for the local development or acceptance of horticulture (Snyder and Gardner 1979). Technologically, the early Middle Woodland Period (ca. 500 B.C. - A.D. 200) in the area is characterized by a thick ware, known locally as Popes Creek, tempered with coarse sand or quartz and always impressed with nets. By late Middle Woodland times (ca. A.D. 200 - 900), a shift to a shell-tempered, often cord-marked or net-impressed ceramic, known locally as Mockley, had occurred. Lithic projectile points associated with the Middle Woodland Period include the shouldered, contracting stemmed Rossville, the lanceolate or stemmed Fox Creek or Selby Bay, the Piscataway, and the corner-notched Jack's Reef (Steponaitis 1980; Wanser 1982). As in the Early Woodland, these projectile point types must be used cautiously as chronological markers. As a final technological note, a marked increase rhyolite use is noted during the Middle Woodland, and is especially associated with the production of Selby Bay lithics (McNett and Gardner n.d.; Custer 1986).
Late Woodland

By the Late Woodland Period (ca. A.D. 900 - 1600), the development of horticulture probably began to achieve a significant role in the total subsistence system, though direct evidence is rare and scattered on the Coastal Plain. Maize, squash, and beans were probably the focus of initial agricultural efforts. The significance of an agriculturally-based subsistence is immense; no other factor is as crucial in the establishment and maintenance of permanent, year-round settlements. Sedentary villages were established near the fertile soils of riverine floodplains (Barber 1979). The presence of smaller, less permanent sites in a variety of settings attest to the fact that other resources were still being exploited.

Artifact sequences were more complex during the Late Woodland, due to several factors, including an increase in ceramic types, and the proliferation of variations of the triangular projectile point. The thin-bodied, sand- or quartz-tempered Potomac Creek ware (Stephenson and Ferguson 1963) and the shell-tempered Townsend series wares (Blaker 1950; Waselkov 1982) are among the most prominent ceramic types. Projectile points include the triangular Levanna and Madison types (Stephenson and Ferguson 1963; Ritchie 1971; Hranicky and Painter 1988).

As the Late Woodland Period progressed, the size and complexity of the villages and settlement systems in the Middle Atlantic increased, characterized by evidence of fortifications, specialized societal roles, development of inter-tribal alliances, growth of intertribal governmental authority and a higher degree of complexity in the observation of religious and ceremonial activities (Barber 1979; Snow 1978).

The east bank of the Anacostia River several kms west of the Kettering Park Site was the site of the village of Nacochtanke when Captain John Smith made his journey up the Potomac in 1608. The people of Nacochtanke, the "Necostins," traditionally have been associated with the Conoy, part of the Algonquin linguistic group, although there is little actual historic or linguistic evidence to support this assumption (Humphrey and Chambers 1977).
IV. HISTORIC LAND USE

Overview of Prince George’s County

European exploration and settlement of southern Maryland was initiated by Captain John Smith’s exploration of the Chesapeake Bay and Potomac River in 1608. His detailed notes of the Indian villages and abundant natural resources encouraged other explorers and traders to the region.

In 1632, Sir George Calvert was granted title to all of Maryland and the southern portion of Pennsylvania. The first colony to be established in Maryland was St. Mary’s in 1634. Sir George was succeeded by his son Cecil, Second Lord of Baltimore. As Lord of the proprietary, Cecil had the right to grant land and collect an annual fee or “quitrent.” Most of the early land grants were acquired by wealthy and influential men, merchants, and planters who intended to increase their wealth through the lucrative tobacco trade.

Cultivating tobacco for trade influenced settlement patterns and the social structure. First, vast tracts of land were necessary for growing the plant, which rapidly depletes the soil. These tracts were located along the shores of the Patuxent, Potomac, and St. Mary’s Rivers, since water transportation afforded the only practical means of reaching trade centers. Second, the potential for great profits from the tobacco trade gave the first immigrants the opportunity for social mobility. For example, during the seventeenth century, most landowners seated their land with indentured servants brought from England. Once these servants completed their period of indenture, they could work as free men and save enough money to purchase their own land and hire their own servants (Wesler et al. 1981:79-82).

By the end of the seventeenth and early eighteenth century, however, the opportunity for social mobility had declined and the social structure had become increasingly stratified. By this time, the native European population (descendants of earlier immigrants) outnumbered the new immigrants. Also, an elite class had emerged from this native population, which continued to consolidate its economic and political dominance. The further decline in new immigrants and indentured servants was caused by the labor shortage in England after 1680. In order to meet the labor demands in the colony, slaves were imported from Africa and soon became an integral element in the tobacco economy. Slavery also contributed to the social stratification within white society because it led to a decline in the status and economic opportunities for free white laborers (Wesler et al. 1981:84).
Kettering Park Site

The population of the region continued to increase, and the need for additional land caused settlement to expand into areas further inland: soon new counties were needed. In 1696, Prince George's County was established out of Calvert and Charles Counties. At this time, the majority of patented land continued to be situated along the riverfronts.

Tobacco remained the primary crop grown in Prince George's County through the eighteenth and into the nineteenth century. During the early eighteenth century, Maryland tobacco was considered to be inferior in quality and could only be traded with Scotland and Whitehaven, rather than the better markets in London. Unrest in the county during the 1730s has been explained by the low price of tobacco at that time (Wesler et al. 1981). In 1747, a tobacco inspection act was passed in order to monitor and improve the quality of Maryland tobacco. Two inspection warehouses were built, one at the mouth of Rock Creek on the Potomac, and the other at the head of the Eastern Branch of the Potomac (now known as the Anacostia) at Bladensburg. The town of Bladensburg had been established in 1742 at a site known originally as Garrison's Landing. The town served as Maryland's leading seaport in the export of tobacco for 50 years (Wright 1977). The project area is located to the northeast of Bladensburg, and it is probable that tobacco grown there was brought to that city for trade.

Several changes occurred in Prince George's County at the end of the eighteenth and early nineteenth century. In 1790, the site of the city of Washington was chosen, and a great portion of the land for the city was ceded by Prince George's County. In addition, the county's population declined as many of the poor white laborers began moving west where more land was available for purchase. The greatest improvement in the vicinity of the project area was the construction of the Washington Branch of the B & O Railroad in 1830. The railroad provided better transportation and encouraged the growth of new towns. Beltsville was established after the rail company purchased the right-of-way for the tracks through Trueman Belt's land.

On the whole, the early and mid-nineteenth century was a period of great stability for the county. Unlike other Maryland counties, crop diversification did not occur. Tobacco remained the most important crop and large plantations tended by slaves were dominant. As late as 1860, for example, there were 60 farms of more than 500 acres, and 58.8% of the county's population was black. During that year, 13½-million pounds of tobacco were produced, the greatest yield for any county in the United States (Wesler et al. 1981:141).

The Civil War dramatically altered the county's economic and social structure. Many of the freed slaves left the county for Washington or Baltimore causing a dramatic labor shortage. This shortage was felt by 1870 when only 3½-million pounds of tobacco were
produced (Wesler et al. 1981:141). Tenancy or sharecropping were the initial solutions for the labor shortage. However, the banks in the Washington and Baltimore provided loans for farmers, which encouraged crop diversification and a transition to smaller, independent farms. Instead of tobacco, farmers cultivated potatoes, fruit, and corn as well as some dairy products, which were marketed in the growing city of Washington. Distribution of these crops to more distant areas became possible by 1880 when refrigerated rail cars were introduced.

The growth of the city of Washington following the Civil War altered land use along the county’s borders. The increasing population and improvements in transportation transformed these areas into suburban neighborhoods. The county’s population grew rapidly, almost doubling between 1900 and 1930, and expanding at even greater rates through the 1960s.
V. OVERVIEW OF FIELD INVESTIGATIONS

Phase I Survey

In 1973, Tom Mayr first reported the Kettering Park vicinity as the location of archaeological materials (Lanham Quad File #2). In 1979, Terrence Epperson directed a Phase I survey of a 300-foot-wide corridor along the southern edge of Maryland 214. The goal of the Phase I survey was to locate and identify any archaeological sites in the project area. The Kettering Park Site (18PR174) was discovered during the survey.

The Phase I investigations at the Kettering Park Site (18PR174) were conducted on July 26 and 27, 1979. Terrence Epperson and Spencer Geasey (Dennis Curry assisted them on July 27th) made surface collections, and six test pits were excavated using both shovels and trowels. Five of the test pits excavated measured 61x61 cms and the sixth measured 46x46 cms. All of the test pits were excavated to a depth of between 46 and 61 cms and the excavated materials were screened through a 1/4-inch mesh. The majority of the cultural material appeared to come from the layer between the dark humus layer on top and the lower, more reddish and sandy layer. Epperson (1979:6) believed that the depth of the units penetrated well into sterile soil.

Epperson's (1979:7-8) artifact inventories from both surface collections and the test pits included the following ceramics: 1 Moyaone sherd, 16 Pope's Creek sherds, and 4 Accokeek sherds. The lithic finds were two quartz Potomac (or Madison) triangular points, one Vernon type expanding stemmed point, three quartz biface fragments, one chert biface fragment, quartzdebitage, quartzite debitage, chert debitage, rhyolite debitage, and a possible hammerstone.

Epperson's (1979:8) attributions of these artifacts led him to believe that the Kettering Park Site was primarily a Late Woodland (ca. 900-1600 A.D.) site that was contemporaneous with the Potomac Creek component of the Accokeek Creek site. He believed that the Kettering Park Site differed from the Accokeek Creek site because it was not a permanent village, but rather a "specialized, short-term occupation" site whose the primary function was the "reduction of lithic materials for the manufacturing of quartz tools, especially quartz projectile points" (Epperson 1979:8).

The lithic materials recovered during the Phase I investigations were later re-analyzed by Carol Ebright, who reclassified the triangular quartz points as Levanna types diagnostic of the early part of the Late Woodland Period. The ceramics from the Phase I excavations were re-analyzed by Katherine Dinnel, who found that the majority of the sherds could be typed as
20 Kettering Park Site

Accokeek, which date to the Early Woodland Period. This information, in combination with the Late Archaic/Early Woodland diagnostic Vernon point, led Kavanagh (n.d.) to conclude that the site was periodically re-occupied from the Late Archaic through the Late Woodland Periods. More complete enumeration of the artifacts will be discussed in following chapters.

Phase II Testing

At the conclusion of the Phase I survey, Phase II evaluative testing was proposed. Testing was considered necessary at the Kettering Park Site because of impending construction plans and because of the site's potential eligibility for inclusion in the National Register of Historic Places (Epperson 1979:8). Maureen Kavanagh, M.A., and Silas Hurry, B.A., carried out Phase II testing from April 12 to May 24, 1983. In accordance with federal regulations, the directors of the field project had adequate training in archaeology, Kavanagh with 6 years of experience in the Middle Atlantic, and Hurry with 9 years of field experience. The fieldwork program was designed to determine both the horizontal and vertical limits of the site, site integrity, the number of occupations, and to evaluate the site's eligibility for listing on the National Register of Historic Places.

During the first stage of testing, 166 shovel test pits (STPs) were excavated in two major blocks across the site. The STPs were placed along transects that were 5 m apart, at intervals of 5 m along each transect. Soil from the excavations was screened through 1/4-inch mesh hardware cloth. All cultural materials were retained and bagged according to provenience. The stratigraphy was recorded during the excavation of each unit.

The spatial dimensions of the Kettering Park Site were determined by the terrain and by plotting the material results from shovel tests. The site was confined to a very specific topographic zone, at the 21.5-22 m contour, at the confluence of the paleocourses of the Northeastern and Western Branches of the Patuxent (Appendix B: Figure 1). Defining the northern site boundary was hampered by the existing roadbed of Maryland 214 and a sewer line north of and parallel to the road (Figure 3). However, the sloping surface that rises immediately behind the sewer line probably marks the northernmost boundary. The site was once farmed (probably in the nineteenth century), then reforested, and more recently cleared for maintaining a park and picnic area. During the investigations, an open stand of trees, mostly beech, was present, containing individual specimens measuring between 25-30 cms in diameter. A gravel
Figure 3
Areas Investigated During Phase II Testing and Phase III Data Recovery Excavations

Kettering Park Site
Kettering Park Site

road ran north to south through the site.

The 11 test units were selectively placed, based on both the artifact distribution and stratigraphic information provided by the STPs (Figure 4). Ten of the test units measured one-meter square and one unit measured 1.5-meters square. The STPs and the 11 test excavation units were excavated by natural layers. The excavation units were subdivided into arbitrary 10-cm levels where appropriate. Areas previously disturbed were eliminated from the grid.

Artifacts

During Phase II testing, 22 temporally diagnostic projectile point fragments were recovered, ranging in age from the Early Archaic to the Late Woodland. Seventeen of the points were given specific type designations. These include three Normanskill, one Lamoka-like, two Bare Island, one Orient Fishtail, one Drybrook Fishtail, one Vernon, three Piscataway, and five Levanna. There were also one untyped Early Archaic, three untyped Late Archaic, and one untyped Late Woodland triangle. Ceramics were recovered throughout the site, but the highest concentrations were recovered from the southern and central sectors. Temporally diagnostic types were recovered from all areas of the site, most of the sherds representing Early Woodland and Late Woodland types. The Late Woodland Potomac Creek, Townsend, and Moyaone wares appeared to be concentrated in the central and southern parts of the site. Artifacts recovered during the Phase II testing also included 16 bifaces and almost 3,000 fragments ofdebitage. More complete enumeration and description of the artifacts is found in the following chapters.

Pedology and Stratigraphy

G. Mathias Kondolf conducted a pedological and geomorphological study at the Kettering Park Site (Appendix B). The study elucidated much about the site’s depositional context and was useful for establishing a general stratigraphy. As Kondolf (1983) notes in Appendix B, the Kettering Park Site is underlain by Quaternary fluvial sands and gravels of the Wicomico Formation (Cooke and Cloos 1951). The surrounding Coastal Plain uplands are primarily underlain by Tertiary Agua greensand, and by less extensive outcrops of the undifferentiated Tertiary Chesapeake group (Cooke and Cloos 1951). The soil at the Kettering Park Site is mapped as Bibb silt-loam (Kirby et al. 1967). The site soils are medium-sized sandy loams and loamy sands, with a gritty feeling (Kondolf 1983).
Kettering Park Site

Figure 4
Site Plan with STPs, Test Units, and Excavated Units Located
Kondolf established a site-wide stratigraphy from auger holes, soil pits, and shovel test pits. Soils were described in the field for color, texture, and consistency. Pronounced thinning and thickening of the A horizon was apparent, probably due to several factors, including sheetwash, sediment trapping, plowing, and disturbance by modern vehicles. The A horizon consisted of two components, an uppermost A1 and an underlying A2. The A1 horizon was marked by a weak-moderate, subangular, and blocky structure. The A2 horizon was characterized as a moderate platey to subangular blocky, very friable, nonsticky, non-plastic to slightly plastic structure, with mottles.

Underlying the A horizon was the B horizon. The excavated units contained developed cambic B and underlying argillic B horizons. The base of the B horizon was marked by the parent material, identified by a change in the soil texture. The parent material primarily consisted of well-sorted fine and medium sand, with infrequent occurrences of silty sand, sandy gravel, and gravelly sand. Within the argillic B horizons the colors were quite red, but the color varied greatly between the units. Thin clay skins were occasionally visible in the B horizon. Below 80 cms in depth mottles were common, indicating that the site was poorly drained. Between 80 and 100 cms in depth an abundance of iron was present in the form of iron oxide-cemented concretions. The available iron was formed by the weathering of glauconite derived from the greensands of the uplands deposited at the site. Development of an argillic B horizon was considered important since stability was indicated. The combination of red color and argillic B development suggested formation ca. 10,000 ± 4,000 years ago.

During Phase II testing, natural stratigraphy was recorded in profiles. The characteristic soil profile consisted of four main natural layers, designated as Strata A-D. A typical soil profile is illustrated in Figure 5. In most units, Stratum A was 3 to 14 cms in thickness, and was composed of a dark brown (7.5YR 3/2 to 10YR 3/3) silt loam. Stratum B was between 5 and 21 cms in depth, with an average at 10.5 cms. Stratum B was a dark brown (7.5YR 3/4, 10YR 3/3) silt loam mottled with a strong brown (7.5YR 4/6) silt loam. Stratum C was a strong brown (7.5YR 5/6) sandy loam or sandy silt loam. Stratum C varied in thickness between 17 and 35 cms, averaging 25 cms. Stratum D was a strong brown (7.5YR 4/6 to 5/6) sandy silt loam.

An attempt was made to correlate the natural stratigraphy with the soil classification scheme (Figure 5). Stratum A was interpreted to be part of the A1 horizon, consisting of a humus of recent age. The late age of Stratum A was indicated by the presence of late historical artifacts in this uppermost layer. Stratum B was also interpreted to be part of the A1 horizon,
Key:

A: 7.5YR 3/2 dark brown silt loam
B: 7.5YR 3/4 dark brown silt loam mottled with 7.5YR 4/6 strong brown silt loam
C: 7.5YR 4/6 strong brown sandy silt loam
D: 7.5YR 5/6 strong brown sandy silt loam
consisting of a mixture of plowzone and intrusive alluvial and sheetwash disturbances, ranging
from finer to coarser texture with depth. The high density of artifacts recovered from the A1
horizon ranged in date from the Late Archaic (2,500 B.C. to 1,000 B.C.) to the late twentieth-
century. Stratum C generally correlates with the A2 horizon. Prehistoric artifacts were
encountered throughout Stratum C or the A2 horizon, with the greatest density occurring at or
near the top. Only one of the 166 STPs contained historical material in level 2 context,
suggesting a minimum of mixing below the plowzone. However, several units had biological
disturbances that included some combination of gullies, roots, root casts, and rodent burrows.
Stratum D was roughly correlated with the B horizon. The B horizon consisted of culturally
sterile subsoil. The B horizon was encountered at a mean depth of 60 cms, but the total range
varied from 42 to 100 cms below the surface. In approximately 30 of the STPs, groundwater
was encountered before subsoil was reached, at a mean depth of 40-50 cms, within a range of
22 to 73 cms in depth. No cultural features were revealed in the test units. However, the test
unit stratigraphy appeared to generally indicate the existence of relatively undisturbed artifact-
bearing deposits below the plowzone.

Phase II Results

The goals of the Phase II testing program were achieved. The Kettering Park Site
limitations were defined by a series of systematic shovel tests and its setting at the confluence
of paleostream courses. While the northern boundary of the site was defined by modern
features, the higher topographic relief just north of Maryland 214 was probably the horizontal
limit of the site. The vertical limitation of the site was clearly established by the excavation of
shovel tests and test units. Strata A and B were considered to be part of the A1 horizon,
representing a mix of plowzone and intrusive alluvial and sheetwash deposits. Stratum C, on
the other hand, appeared to be a relatively intact A2 horizon. Stratum D was underlying the A2
horizon and was clearly identifiable as an ancient B-horizon. The uppermost A1 horizon
contained a mix of historic and prehistoric artifacts, whereas the A2 horizon appeared to
represent higher integrity deposits with mostly Late Archaic and Early Woodland material. Of
the temporally diagnostic materials from the A1 and A2 horizons, the Late Archaic, Early
Woodland, and Late Woodland Periods appeared to be most abundant. The density of ceramics
and chipped stone clearly indicated that data could be obtained about material economies. The
density and diversity of Early Woodland ceramics was of particular interest, and was considered
to be useful for examining ceramic traits. While no features were identified, the discovery of
artifacts in the A2 horizon was considered important, useful for addressing issues relating to
prehistoric settlement and technology.
Phase III Data Recovery

Research Design

Upon completion of the Phase II investigations, more intensive excavations were recommended because the data analysis determined that subplowzone deposits with mostly Late Archaic and Early Woodland materials were present at the site. The Maryland State Highway Administration and the Maryland Historical Trust agreed that the Kettering Park Site was eligible for listing on the National Register of Historic Places under Criterion D, the site having the ability to yield information to prehistory. Although Maureen Kavanagh prepared a draft report of the Phase II work, it was not completed due to the imminence of Phase III excavations. General research goals for the Phase III field work were developed to address prehistoric settlement and technology themes of the Maryland Comprehensive Historic Preservation Plan. More specifically, the goals of the Phase III research were 1) to obtain a representative collection of artifacts associated with the Early Woodland Accokeek occupation of the site; 2) to provide specific statement concerning activities at the site; 3) to provide detail on the extent, direction, and nature of lithic exchange systems operating in the Early Woodland period relative to earlier and later periods; and 4) to formally define three varieties of Accokeek ceramics.

Phase III Excavation

The Phase III excavation was conducted in the same area as the Phase II Testing, at the 21.5-22 m contour (Figures 3 and 4). The primary purpose of the Phase III excavations was to recover a representative sample of Early Woodland artifacts from the subplowzone A2 horizon. The portion of the site lying within the construction area that had the best preservation of this stratigraphic zone was delineated. Since no features were found, and since the purpose of the Phase III was to obtain a representative sample of Early Woodland material, a random sampling strategy was deemed most appropriate. A 10% sampling level was selected, based upon tests of sampling percentages at St. Mary’s City which determined that a 7.5% sample was sufficient to characterize a site in terms of both site activities and artifact assemblage (Henry Miller, pers. comm. with Maureen Kavanagh, 1985). Two-meter square units were chosen to maximize coverage, thereby increasing the reliability of the random sample (Redman 1975:151). The selected excavation units consisted of a 10% non-aligned, stratified, random sample. If a selected unit contained a standing tree, another was randomly chosen as a replacement. Avoiding trees in the southernmost zone was necessary because the site was located in a public park.
Kettering Park Site

The humus and the plowzone/wash layers were excavated by removing (by shovel) and screening of the northwest quadrant of each unit. The remaining three quadrants were removed without screening. Grab samples of both historical and prehistoric artifacts were collected from the excavated material. The units were divided into four one-meter square quadrants in order to maintain greater control of the provenience of the recovered materials. The 13 units were excavated (by trowel) in natural layers that were divided into arbitrary 10-cm levels where their depth permitted.

Universal Stratigraphy

To establish a universal stratigraphy for the phased archaeological investigations, and a proper analytical framework for artifact studies, the strata of the Phase II test units were correlated with the strata of the Phase III excavated units. The Phase II test units were excavated by arbitrary 10-cm levels, and natural stratigraphy was recorded in the profiles. The Phase III excavated units were dug in natural layers. In each excavation, subplowzone deposits were identified, and were grouped as belonging to the A2 horizon. Table 1 represents a universal level designation for the A2 horizon. The table shows both the absolute elevation above sea level for the top of the A2 horizon, and the levels that constitute this stratum for each site unit.

Table 1 demonstrates a correlation between changes in the slope of the site with elevation changes in the top of the A2 horizon for both Phase II test units and the Phase III excavated units. This correlation allowed the stratigraphy and subsequent mapping of the A2 horizon artifacts across the site to be standardized.

VI. LABORATORY METHODS

Artifact Processing

All artifacts recovered during the three phases of research at the Kettering Park Site were transported to the Maryland Geological Survey archaeological laboratory for processing. The lithic artifacts selected for special analysis were curated in an unwashed condition so as not to destroy any possible residues. The remaining artifacts were cleaned. All artifacts were organized by provenience and a unique lot number for each provenience was assigned. Tools, cores, and sherds were assigned unique consecutive numbers within each provenience; this number was appended to the lot number as a decimal. The provenience data were computerized using dBase III+ software.

Artifact Cataloguing

All artifacts recovered from the Kettering Park Site were re-catalogued after 1988 using a technologically based cataloguing system developed in 1987 by Carol Ebright. The artifacts were catalogued by lot and according to deliberately general classification categories. The broadly defined categories were designed to maximize the ability to extract sets of related artifacts for further analysis as a group. More complete recording of relevant attributes for particular classes of artifacts was accomplished during subsequent analysis. Only fire-cracked rock was weighed, counted, and discarded; the remaining prehistoric artifacts were curated.

Technological classification was utilized as a means of better understanding the lithic and ceramic technologies used at the site. An original goal of the Phase III research was to formally define three varieties of Accokeek ceramics. The cataloging system was designed to record the compositional attributes that would define three distinct wares. The technological analysis of the lithic artifacts was based on a system that distinguished between ground stone tools, tools whose morphology was created primarily through use, and those produced by bifacial, unifacial, and bipolar flaked stone technologies.
Debitage Analysis

Debitage includes flakes, cores, and chunks, all waste products of the flaked stone tool manufacturing process in either bifacial, unifacial, or bipolar reduction trajectories. The recovered debitage was catalogued using Ebright's (1985, 1992) criteria. The debitage categories used in cataloguing the artifacts are defined below.

Flake - A flake is defined as any piece removed from a core or tool. Any one of the following criteria can be used to define a flake: a striking platform, bulb of percussion or sheared Hertzian cone, conchoidal fracture ripples, a hinge termination, or the presence of flake scars on the dorsal surface. Large, heavy flakes with dorsal flake scars indicating that the artifact was probably a large part of a core are still considered flakes unless there is evidence that the flake itself was used as a core after it was produced from the parent material. The following flake types are produced in bifacial and unifacial reduction technologies.

Decortication Flake - Any flake containing cortex is included in this category except those with bipolar characteristics. "Cortex" includes bedding plane surfaces as well as nodular rinds. Platforms are often flat and triangular in shape and have often been prepared by removal of small flakes near the dorsal platform surface to isolate the platform and even the sides.

Primary Flake - Primary flakes are characterized by a single or double ridge on the dorsal surface produced by the removal of previous flakes. The horizontal cross-section is usually triangular. Platforms have often been modified in order to isolate them and may be either flat or faceted. Grinding is often present. The bulb of percussion is frequently pronounced, often giving the ventral flake surface of short flakes an overall convex shape. Longer flakes are often twisted and curved in longitudinal cross-section, indicative of attempts to remove ridges and angularities.

Secondary Flake - Secondary flakes are often referred to as biface thinning flakes. These are characterized by complex flake scars on the dorsal surfaces, a thin lenticular horizontal cross-section, and a thin, slightly curved or flat longitudinal cross-section, and a thin, slightly curved or flat longitudinal cross-section. Striking platforms have usually been carefully prepared, are lenticular in shape, faceted, and ground.
Tertiary Flake - Tertiary flakes are small, thin flakes with most of the characteristics of secondary flakes. Generally about 1/4-inch wide and 1/2-inch long or less, tertiary flakes represent the final stages of thinning and shaping a tool. Those flakes produced by percussion tend to be flat in longitudinal cross-section; those produced by pressure tend to be slightly twisted and show a greater curvature. Platforms are nearly always lenticular and ground, and dorsal flake surfaces show a complex pattern and flake scars.

Multifacial Flake Core - A core characterized by removal of flakes of uncontrolled shape for expedient use, or modification in a bifacial or unifacial trajectory. Multifacial flake cores can have a single platform area, bifacial flake removals, or randomly placed platforms related to the morphology of the raw material.

Bipolar manufacturing technologies produce the following debitage types:

Bipolar Flake - Bipolar flakes, with and without cortex, are characterized by a Hertzian cone rather than a bulb of percussion. This appears as a flat surface, often with visible compression rings. The platform is usually crushed and concave, as is the end opposite the platform. Dorsal flake scars are often parallel, linear, and frequently do not emanate from the striking platform, as is characteristic of non-bipolar flakes.

Bipolar Core - A core characterized by one or more paired, crushed platforms exhibited sheared Hertzian cones. Platform pairs may be oriented in several directions, sometimes with one point or area serving as the point of impact or anvil contact for several opposing platforms. Bipolar cores range from split cobbles that serve as biface blanks, to randomly reduced cores from which flake blanks were produced, to piece esquilles which may represent either exhausted bipolar cores or tools.

Debitage that cannot be related to a particular technology includes:

Chunk - A chunk is characterized by freshly broken surfaces, but lacks clear negative flake scars to confirm that it was a produced by human activity. Chunks are usually produced in the earliest stages of tool manufacture, and often occur as a result of internal flaws in the raw material.
Kettering Park Site

Microflake - A flake smaller than ¼ square inch that is broken to the extent that its type cannot be determined. This category was used only with debitage recovered from flotation.

Unclassifiable Flake Fragment - A flake broken to the extent that its type cannot be determined. This classification includes debitage recovered with 1/4-inch screens.

Unclassifiable Core Fragment - A core broken to the extent that its type cannot be determined. However, all core fragments have evidence of at least one negative flake scar.

Core Analysis

All cores were individually examined, and metric attributes recorded include weight, maximum length, and maximum thickness. Platform type for each type of core, degree of exhaustion, material quality, and cortex presence and type were also evaluated.

Uniface Tool Analysis

Unifacial tool analysis included the determination of one or more working edge angles; the combined length of the working edge; and length, width, and thickness measurements. Formal unifacial tools and retouched/utilized debitage are considered part of the unifaces, even in some cases where retouch was bifacial.

Biface Analysis

All non-diagnostic bifaces were individually examined. Length, width, and thickness measurements were taken, and the width/thickness ratios were calculated to determine the stage of manufacture. Biface stage definitions were adapted from Callahan’s (1979) replicative studies.

Bifacial Tool Manufacturing Errors

An aspect of lithic biface analysis involves the ability to distinguish failed attempts at tool manufacture from those broken postdepositionally. Analysis of breakage patterns provides a means of assessing these factors, and can yield clues to the manufacturing techniques employed
as well as the stages in which tools were manufactured, used, and recycled. The definitions of these terms are provided below and were extracted from Kavanagh and Ebright (1988) and Ebright (1992).

Manufacturing Errors

**Thinning Failure** - Thinning failure manifests itself as a surface irregularity, usually as a hump on one face, surrounded by flake scars terminating in hinge fractures. This error does not necessarily result in breakage although attempting removal of humps is a major cause of perverse fracture described below. Hinge fractures, in these instances, may be caused by flaws in the material, and contribute to the decision to abandon the artifact. While thinning failure may result in an unusable projectile point, it does not necessarily prevent the use of the artifact in another, more general, function.

**Material Flaw** - Material flaws consist of a variety of imperfections in a lithic material including bedding planes, fossils, crystal pockets, and other inclusions. Major flaws usually cause fractures during the manufacturing process as a result of vibrations created during knapping. This is one of the primary ways that chunks and shatter are produced. Artifacts with minor flaws may survive the manufacturing process, but the flaw may later contribute to tool failure during use.

**End Shock** - End shock is a fracture pattern that occurs late in the manufacturing process after a biface has been partly thinned. This fracture occurs at the point other than where the biface is struck by the percussor, and is the result of vibrations exceeding the tensile strength of the material. End shock fractures usually occur perpendicular to the long axis of the biface, usually at the tip end, and have a distinct "S" shape on the fracture surface when viewed from face to face.

**Perverse Fracture** - Perverse fractures are diagonal transverse breaks that occur during biface thinning as a result of excessive force and/or misplaced platforms or billet blows. Fracture surfaces are twisted when viewed from edge to edge. Perverse fractures are frequently associated with thinning failures, especially those centered on biface edges. Many also occur in conjunction with material flaws.
Reverse Hinge Fracture - This fracture type is most often associated with attempted end thinning during manufacture. Bifaces fractured in this manner exhibit a rounded break on one half where the thinning flake removal attempt curved through the body of the biface. The other half retains the negative concavity and often a "tail" containing the original striking platform.

Use-Related Errors

Impact Fracture - Impact fractures are probably the most commonly recognized use-related breakage pattern. They are characterized by one or multiple flake scars emanating downward from the tip, often accompanied by removal of blade margins around the tip. Tips are occasionally pulverized resulting in a horizontal or slightly concave break with a battered edge similar to that seen on a bipolar core. Impact-related flake scars often exhibit sheared Hertzian cones.

Haft Snap - Haft snaps result from the application of excessive force to the blade of a biface, in a face-to-face or edge-to-edge direction. The consequent fracture occurs at the point of least support - the juncture of the haft element and the blade. This fracture pattern is most likely to occur in uses other than as a projectile.

Margin Spall - Margin spalls occur as a result of the tendency of force to follow existing ridges on the topography of the artifact. The most acute ridges on bifacial artifacts are the edges, and margin spalls occurring by themselves are usually an indicator of the use of the artifacts as a knife, and occur when the edge encounters a hard substance such as bone. This fracture type also co-occurs frequently with impact fractures.

Twist Fracture - Twist fractures most frequently occur on the blade portion of biface and are characterized by large flake removals on opposing sides and faces of the resulting fragment. They result from artifact use in a non-projectile point function.
**Thermal Errors**

**Crenated Fracture** - Crenated fractures exhibit a distinctive curved and/or wavy fracture surface and result from the application of excessive heat or too rapid heating or cooling. This error usually occurs during intentional heat treatment of bifaces.

**Crazed, Spalled, or Exploded** - These errors are evidence of thermal damage that may have originated from either errors during intentional heat treatment or [exposure to] postdepositional fire. Crazing consists of irregular internal fracturing that effectively prevents further modification. Explosion and spalling result in physical fracturing, exposing large areas of crazed surfaces. Pot lid fractures are circular spalls that pop off chert surfaces during the initial stages of heat damage. Pot lid fracturing does not necessarily impede further flintknapping if it occurs on a small scale. In general, the above listed thermal fractures are more catastrophic in nature than crenated fracturing, and are less reliable indicators of intentional aboriginal heat treatment of lithic materials.

**Bipolar Fractures**

Bipolar fractures are defined by the presence of two crushed platform areas and the presence of a flat and sheared cone surface rather than positive or negative bulbs of percussion on interior surfaces. Bipolaring on bifacial artifacts appears to occur most often on already broken biface fragments and frequently occurs in a side-to-side direction. Occasionally bipolaring occurs in an end-to-end direction on apparently complete artifacts. In the former case, enough bifacial attributes are retained to distinguish these from bipolar cores or pieces esquillees. In the latter, opposing platforms distinguish bipolar ed implements from impact-fractures artifacts. The reasons for creating bipolar ed biface fragments are not clear.

**Diagnostic Bifacial Artifact Types**

Identifying diagnostic artifacts by type attempts to isolate and determine the cultural and temporal affiliation of particular components. Projectile point classification was undertaken using original published type descriptions and comparable points from documented contexts. Both metric and descriptive attributes for projectile points were taken.
38 Kettering Park Site

Ground Stone and Use-Modified Stone Tool Analysis

Standard length, width, and thickness measurements were taken on all artifacts in these categories. In certain cases, specific working surface types and locations of wear were also identified.

Fire-Cracked Rock

Fire-cracked rock were counted and weighed to provide an estimate of mass for mapping and analytical purposes.

Lithic Raw Materials

The great majority of the lithic artifacts were made from quartz, quartzite, rhyolite, and chert. Quartz was broadly defined to include translucent or opaque material of massive character, or which exhibited heterogeneous surface textures. Quartzite was narrowly defined to include materials that were opaque and exhibited consistent, uniform granulation. Quartz and quartzite were locally available from the immediate vicinity of the site, in secondary deposits. Rhyolite was a distinct material but exhibited various gradations. Rhyolite deposits are located in the Blue Ridge deposits in Maryland and Pennsylvania. Cherts were a distinct material, but there was variation in color and structural characteristics. Cherts could be derived from primary sources or secondary gravels.

Ceramic Analysis

The attributes used for the recording of these artifacts included temper, surface treatment, and vessel portion when apparent. Vessel thickness, paste texture, and cord-twist direction were also recorded. The surface treatment that produced as a result of the manufacturing technique was differentiated from those that were applied as decoration.

Curation

All artifacts, field records, and photographs from the Kettering Park Site will be curated at the Maryland Historical Trust facilities.
VII. ARTIFACT ANALYSES

Table 2 provides the count and frequency of all artifact classes recovered during the Phase I, II, and III investigations at the Kettering Park Site. Appendices C and D represent the artifact inventory codes and a full artifact inventory. A total of 6,662 prehistoric artifacts was recovered from the three phases of archaeological investigation at the Kettering Park Site. The artifacts consisted of 1,048 ceramics, 826 fire-cracked rocks, and 4,788 stone artifacts. In the following section, the ceramic and stone artifacts are discussed by morphological types, providing detailed descriptive information for analytical purposes.

Ceramics

A total of 1,048 ceramic sherds was recovered during the survey, testing, and excavation of the Kettering Park Site. A list of ceramic attributes and measurements appears in Appendix E. Ceramics accounted for 15.7% of all prehistoric artifacts recovered. The sample discussed here was restricted to 818 sherds because fragments that measured under 1 sq cm were identified by paste and surface treatment and were excluded from further analysis. Where possible, sherds were cross mended, and in one case 96 sherds were partially reassembled into a single Accokeek Creek micaceous sand-tempered vessel\(^1\). In the original analysis, mended pieces were counted as a single piece, and as a result the total sherd count, less the minute fragments, was 723. However, since this single micaceous sand-tempered vessel was extraordinary, counting the sherds as "one" cross-mended piece skewed the overall percentages. As a result, it was decided to include the 96 individual sherds in the overall count of 818.

In total, 83.7\(^2\)% of the ceramics studied were dated to the Early Woodland Period. The types present included Marcey Creek, Selden Island, and three varieties of Accokeek ware. All of the ceramic types and the method of their classification are discussed in detail below. The only Middle Woodland ceramic type represented was Mockley ware; this type accounted for

\(^1\)Most of the sherds had very eroded edges. The conjoining of eroded edged pieces to form a partial vessel did not provide information adequate to determine vessel form or dimensions.

\(^2\)Using the original sample number of 723, the Early Woodland ceramics comprise only 70.5 percent of the assemblage; the Middle Woodland sample accounted for 10.5 percent; and the Late Woodland Period percentage remained unchanged.

1.5% of the ceramics recovered (11 sherds). It should be noted that 65 "unidentified shell-tempered" fragments were recovered, but Dinnel and Kavanagh (1990) felt that these could either be Mockley (a Middle Woodland diagnostic) or Townsend (a Late Woodland diagnostic) wares. These fragments have been classified as "unidentified" in the ceramic classification summaries so as not to skew the sample.

Five Late Woodland types were recovered during the three phases of investigations at the Kettering Park Site: Townsend, Moyaone, Potomac Creek, Shepard, and Riggins wares. The sample also included 21 sherds that dated to the Late Woodland Period (the attribution was based on the density of the paste, the hardness of the fire, and the thinness of the vessel walls) but could not be classified according to type. In total, 12.6% of the ceramics recovered dated to the Late Woodland Period.

Of the ceramics which could be classified to a specific type (n=460), 78% were Early Woodland, 19.6% were Late Woodland, and 2.3% were Middle Woodland (Figure 6).

[Percentage of Total]
A total of six Early Woodland ceramic types was identified (Figure 7). Most of the ceramics were one of three varieties of Accokeek types, with several sherds of Marcey Creek and Selden Island types. Although 151 sherds were unidentifiable as to type, they could be assigned an Early Woodland date.

**Marcey Creek Ware**: Two body sherds of Marcey Creek were recovered; both of these appear to be from near the base of a thick vessel that was made by using the slab-construction technique. The paste of this vessel type is friable, chunky, and has a soapy texture. The non-plastic inclusions are crushed steatite, and medium grained micaceous sand. The thickness of the vessel(s) represented in this sample ranged from between 11.4 and 14 mm. The two sherds that were recovered were undecorated and had a smoothed exterior with an uneven wavy appearance (Dinnel and Kavanagh 1990; Manson 1948; Egloff and Potter 1982).
Selden Island: Three body sherds tempered with crushed steatite were found. The temper size was generally less than 1 mm, but a 10-mm chunk was also present. The paste of these sherds was hard, compact, and had a soapy texture. All three of the recovered sherds were cord marked. Impressions on one of the sherds indicated that a thin, close set cord, between 1- and 2-mm thick, was used for marking (Dinnel and Kavanagh 1990).

Accokeek Ware: Many ceramics were identifiable as Accokeek ware. The estimated dates for Accokeek materials in the lower Potomac drainage is 800-300 B.C. (Egloff and Potter 1982). Accokeek rim sherds share many similar stylistic and technological characteristics although there is some degree of variability in rim profiles, lip treatment, and surface treatment (Figures 8 and 9; Table 3). It should be noted that while a goal of the study was to formally define Accokeek types, the sample size did not allow for such a typology (Maureen Kavanagh, pers. comm., September 1993). While this was the case, three varieties of Accokeek ware were recovered, and designated as Accokeek "cord-marked," Accokeek "coarseware," and Accokeek "micaceous sand-tempered." The total number of identifiable Accokeek sub-types found was 449. These sub-types may eventually prove to be of some use for typology once more data is obtained from other sites. The sub-types are broken down by variety below.

Accokeek Cord-Marked: In total, 11 rim sherds, 1 base, and 222 body sherds were found. Of the 11 rim sherds, most exhibited straight profiles (Table 4). Of the 12 pieces in which lip treatment could be identified, there was some degree of variation (Table 5). The paste of this type is friable, coarse, and has a very sandy or gritty texture. This sample included the following paste colors: orange, red, tan, brown, grey, and black. Most of the sherds were variegated in color due to poor control of the firing temperature, and uneven oxidation. The density of sand in the paste ranged from 5-50%, with the mode between 30 and 40%, and the mean of 35%. The vessel thickness ranged from 4.4 to 10.1 mm, with a mean of 6.82 mm.

As indicated by the name of this type, all of the sherds had cord-marked exterior surfaces. The marks were applied by the use of a cord-wrapped paddle. The cord used appears to have been 98.5% S-twist, and 1.5% Z-twist, loosely twined, and 1-2-mm thick. The cord spacing was often irregular and ranged from 2-4 mm. The marking design usually angled downward (away from the rim) at less than a 45 degree angle. The cord impressions were crossed occasionally or angled downward and left of the rim. Eight of the sherds (3.4%) were marked by a paddle that was wrapped with overlapped crossed cords, and appear similar to net impression, but no knots were present. A single sherd was decorated with incision (Dinnel and Kavanagh 1990).

Accokeek "Coarseware": In total, 119 sherds of this type were recovered: 4 rim sherds, 2 bases, and 112 body sherds (Figure 10). Rim treatment, lip treatment, and surface treatment could be determined on several sherds (Table 3). This type differs from the Accokeek cord-marked variety in that it is less sandy in texture, and the cord used for the surface treatment is coarser. The non-plastic inclusions in the Accokeek "coarseware" paste are sand and crushed quartz. The crushed quartz ranged in size from 1-11 mm with a mode of 4 mm. The paste of this ceramic type is chunky, moderately compact, and gritty or rough in texture. The percentage of sand present in the paste ranged from 5-50%, with a mean of 21%.

The vessel thickness represented in the sherds recovered ranged from 4.6-10.4 mm with a mean of 7.24 mm. The surface was cord-marked; a cord-wrapped paddle was used to pattern the surface of the vessel when the clay was still plastic. Cord with an S-twist that was between 1-4-cm thick and spaced 2-5 cm apart was used. The cord-marked pattern generally angled downward and to the right from the rim at an angle of 20 to 40 degrees. The range of cord-marked patterning included the application of the design downward and to the left, and
Source: Engineering-Science

Kettering Park Site

Figures 10
Accokeek Rim Sherds
occasionally in a direction that parallels the rim. The majority of the interiors were hand smoothed, but a few were scraped. All recovered fragments were undecorated.

Accokeek "Micaceous Sand-Tempered": Two rim sherds and 94 body sherds of a single vessel were recovered (Figure 10). The paste of this vessel has a sandy texture, is slightly friable, is fine-grained, and is tempered with micaceous sand. All exterior surfaces glitter due to the mica present in the paste. Vessel thickness ranged from 4.95-7.1 mm with a mean at 6.54 mm.

The exterior surfaces were cord-marked, by a paddle wrapped with fine S-twist cord. The cord width was between 1 and 2 mm and the wrapping was set 1-4 mm apart. The cord-marked pattern ran parallel to the rim. Interior surfaces were hand smoothed. The vessel was undecorated but the surface of the rim edges were marked with the edge of the cord-wrapped paddle. This vessel is similar to Type D, micaceous sand-tempered pottery from the Accokeek Creek site (Stephenson and Ferguson 1963:127). It was recovered from three contiguous excavation units, and an adjacent STP. The rim sherds were thinned, straight, and everted at the lip (Dinnel and Kavanagh 1990).

Unidentified Early Woodland: A single rim and 150 body sherds were found that had a sandy gritty texture and a coarse, friable paste. The temper was medium to coarse sand and in some cases crushed quartz was also present. All exterior surfaces were too eroded for classification, and the interior surfaces were either eroded or smoothed (which is non-diagnostic). The range of thickness was from 3.7 to 10.4 mm, with a mean of 6.86 mm. Paste color was various mixed ferruginous oranges and dark greys.

Dinnel and Kavanagh (1990) originally believed that there was a relationship with Popes Creek pottery, but when they compared them to Accokeek assemblages the similarities were far greater. They classified these sherds as dating to the Early Woodland based on the texture of the paste, the color, and the mean thickness of the sherds. They concluded by stating that "connections with the Accokeek ware are reinforced by the absence of any identifiable Popes Creek ceramics at this site" (Dinnel and Kavanagh 1990).

Middle Woodland Ceramics

Mockley Ware: A single base and 10 body sherds of this Middle Woodland ware were recovered. This type dates to A.D. 200 - A.D. 800 (Egloff and Potter 1982). These few sherds
50 Kettering Park Site

and was chunky and friable; it was tempered with shell that had leached out. The thickness ranged from 6.9-16.7 mm; the mean thickness is 9.15 mm. Eight of the sherds had net impressed surface treatment, the mesh was composed of many small knots evident in the surface impression, and no decoration was present (Dinnel and Kavanagh 1990; Stephenson and Ferguson 1963).

Late Woodland Ceramics

Townsend Ware: In total, 53 sherds of this type were recovered including 1 rim sherd and 52 body sherds. The paste of Townsend Ware is fine-textured; the fine shell temper had been leached out, but the holes that remain are aligned. The texture of the paste ranges from chalky to sandy; the sandy paste had a higher grit content. The surface is paddled and fabric impressed.

The fabric used for the surface impression appears to have been a weft-face weave, with a thin flexible weft made of twisted cord and a warp that was moderately rigid. The width of the weft threads was 1-2 mm, and the width of the warp threads was 5-9 mm. The interior was frequently smoothed and occasionally scraped. Twenty of the sherds recovered had evidence of smoothing, and 15 were too eroded to determine whether they were decorated.

In addition three sherds were decorated with two or three incised lines. The presence of these incisions suggests that they date to the first half of the Late Woodland Period between A.D. 900 and A.D. 1250 (Griffith 1982). The single rim sherd was scalloped (Dinnel and Kavanagh 1990; Blaker 1950; Stephenson and Ferguson 1963; Egloff and Potter 1982).

Moyaone Ware: Six body sherds of this Late Woodland ware were recovered, which dates to the final part of the period, A.D. 1350 to A.D. 1600 (Stephenson and Ferguson 1963; Egloff and Potter 1982). The paste is fine, compact, smooth-textured, and tempered with fine micaceous sand. The body thickness ranged from 4.5 to 7.15 mm with a mean of 5.8 mm. The surfaces of all recovered sherds were plain (Dinnel and Kavanagh 1990).

Potomac Creek Ware: A single body sherd of this ware was recovered. Potomac Creek ware dates to the latter half of the Late Woodland Period A.D. 1300 - A.D. 1700 (Stephenson and Ferguson 1963; Egloff and Potter 1982). The paste is finely made, compact, hard, and had a sandy texture. The thickness of the sherd was 6.2 mm, and its surface was cord-marked. The
temper was fine sand mixed with crushed quartz, and the interior of the vessel was oxidized (Dinell and Kavanagh 1990; Stephenson and Ferguson 1963; Egloff and Potter 1982).

**Shepard Ware:** Five body sherds tempered with crushed quartz and made of clayey dense paste were recovered. The thickness ranged from 4.0 to 7.0 mm, and the surface was marked by a cord-wrapped paddle. One of the sherds recovered was from the collar portion of a vessel. Shepard ware dates to A.D. 900 - A.D. 1450 (Peck and Bastian 1977; Kavanagh 1982; Stewart 1982; Dinell and Kavanagh 1990).

**Riggins Ware:** The total number of fragments recovered was 16 body sherds. The paste has a sandy/gritty texture and is compact; the temper is gneiss/schist and/or quartz. Eleven of the sherds were fabric impressed and looked very similar to Townsend ware. Surface smoothing was present on two of the sherds; the remaining three were badly eroded. Vessel thickness ranged between 4.0 and 9.0 mm, with a mean thickness of 6.3 mm. Riggins ware dates to the second half of the Late Woodland Period (Lopez 1971; Kavanagh 1982; Dinell and Kavanagh 1990).

**Lithic Artifacts**

This section presents technological descriptions of all classes of stone artifacts. A total of 4,788 stone artifacts was recovered from the site. The stone artifacts represent 71.8% of the total prehistoric artifacts recovered. Since the Kettering Park Site contained a large number of stone artifacts, much attention was given to describing and analyzing the assemblages.

The lithic assemblages were organized into standardized categories, thereby providing a basis for intrasite and intersite comparative analysis. Lithic tool manufacture is a reductive process, involving the removal of material until a desired or appropriate form is reached. The analysis therefore focused on the varieties of tools produced and on the debris resulting from the manufacturing process.

The projectile points were classified into standard stylistic typologies of the eastern United States. Assignment of projectile points by morphological types provided information on the period of site occupation, and point attribute measurements provided intersite comparative information. To characterize the technologies employed at the site, all of the stone industries were classified into bifacial, unifacial, and bipolar categories. Flake types were examined to determine the quantity and stages of tool manufacture. Classifyingdebitage by type identified the kinds of items manufactured and maintained on the site. Lithic raw materials were studied
52  *Kettering Park Site*

by artifact type to provide information about prehistoric selection and use of stone. The diagnostic artifacts were made from local secondary lithic sources and more distant secondary sources, hence trends by chronological period were studied to discover trends in the temporal patterning of raw material selection. Functional determination of the tools was based on a various lines of evidence, including gross morphology, breakage patterns, edge angles, and residues.

The following discussion is divided by morphological categories. Where appropriate, the categories are subdivided into further hierarchical unit for descriptive and analytical purposes.

*Bifacially Flaked Stone Tools*

Bifacially flaked stone tools consists of Projectile Points, Projectile Point Fragments, Stage 1-3 Bifaces, and Unclassifiable Biface Fragments. A list of biface measurements appears in Appendix F. Table 6 quantifies bifacial types by the materials utilized for their manufacture. Quartz and quartzite are the most frequently used materials for the manufacture of all bifaces. The projectile points consist of a greater diversity of raw material types. The Stage 1-3 bifaces are represented by quartz and quartzite, probably local raw materials. In the following sections, more specific information about projectile points and raw materials is presented.

*The Projectile Points*

The projectile point types are discussed in order of temporal subdivisions. Specific projectile point types are presented alphabetically within each temporal group. The projectile points are compared to other Northeastern and Middle Atlantic sites. If a projectile point type consists of a single specimen, an illustration is provided, and where greater than one specimen, photographs are provided.

Raw Material: 1 quartz, 2 quartzite

Description: This projectile point type tends to have a narrow triangular blade, and all of the examples from the Kettering Park Site had slightly concave bases. All three of the specimens of this type were nearly complete; one was missing its tip and the other two were missing a basal corner. The quartz projectile point had a very narrow and sharp tip that may indicate its use as a graver or perforator; its blade was bevelled. This projectile point also had a margin spall, and both its stem and sides were ground. One of the quartzite specimens was exceptionally thick near its tip, with one straight side and one concave side due to resharpening. This projectile point also had grinding on its base and notches, and its tip was broken at an impact fracture. The other quartzite specimen appears to have been resharpened and exhibited severe hinges along both sides due to thinning failures. This projectile point displayed moderate grinding along its base and stem. Although two of the three specimens bore evidence of grinding, such hafting element modification is a rare feature on Normanskill points (Ritchie 1971).

Chronology: Ritchie (1971) dates this projectile point type to the Middle Archaic (6,500-2,500 B.C.). According to Ritchie (1971), Normanskill points are an element of the Vosburg complex of the Laurentian tradition. In his view, these points are a morphological transition between Lamoka side-notched points and Brewerton side-notched points.
Kettering Park Site

Figure 11
Normanskill Points
Comparative Data: Ritchie (1971) reported New York projectile points had lengths that ranged from 35-67 mms, most falling between 40-49 mms; and a thickness that ranged from 4.6-9 mms with the majority at 6 mms thick. The distribution of this type in New York clusters along the Hudson River and its tributary streams. They have been found at the following New York state sites: the Harris site in Saratoga County, the Lotus Point site in Green County, and a large sample (number not provided) at the Vosburg site in Albany County. The Kettering Park Site examples are at the small end of Ritchie’s dimensional ranges, except in terms of thickness.

* Length of incomplete tool

Raw Material: 1 quartz, 2 quartzite

Description: Projectile points of this type have triangular blades, with shoulders that range from sharp to slightly rounded. The points are generally symmetrical and tend to be thick in cross section when they are made of quartz or quartzite (such as those in this sample). The specimens in this sample were of three disparate sizes, and each had a slightly different stem. One quartzite point had a contracting stem with a flat base, the other quartzite specimen had a
Source: Engineering-Science

Kettering Park Site

Figure 12
Bare Island Points
rectangular stem with a concave base (the sharp bevelling of its blade made the stem appear to twist); and the quartz point had a stem with slightly concave sides and a straight base that was missing a very small piece of one corner. The quartz point had a rounded tip that appears to have been formed in three stages: at some point during its use the narrow tip of this point apparently was broken off; this break was then reworked through pressure flaking and the tip became broader; then at its last usage, the tip appears to have been damaged again. The remnant tip has evidence of reworking near one edge, and damage (perhaps through impact) at the other side of the tip. The blade also contained a margin spall, the base had been thinned, and the stem had been ground slightly.

The larger quartzite projectile point had its tip snapped off in one sharp, clean break. This point also exhibited many step fractures along its blade and at its shoulder, and had a margin spall. The base was thinned but not ground, and the edges of the blade had been resharpened. The remaining quartzite projectile point was nearly complete, missing only one shoulder, had a sharply bevelled blade, and a narrow distal end with only a small fraction of its tip missing.

Chronology: Ritchie (1971) dates this point type to the Late Archaic (2500-1000 B.C.). It is contemporaneous with the use of steatite bowls, based on reports from numerous sites on the Lower Susquehanna River, and at the Kent-Hally and Fallen Tree sites on Bare Island.

Comparative Data: Ritchie (1971) reported that Bare Island points have been found throughout New Jersey and into eastern New York. Areas with particularly large samples include Staten Island, Long Island, and along the Hudson Valley to Saratoga County (at least). One site in Green County (Ctl.1) provided a sample of 114 points. The specimens from New York ranged in length from 29-93 mms (mean=49); the reported widths ranged from 1/3-1/2 of the total length. Stephenson and Ferguson (1963) reported a sample of 269 specimens from the Accokeek Creek site with lengths ranging from 45-83 mms (mean=69), and widths from 16-30 mms (mean=21). Thicknesses ranged from 8-15 mms (mean=12). Bare Island points are Kinsey’s (1959) "straight stemmed, Type A." Specimens from the Kettering Park Site are both above, below, and within the size range provided by Stephenson and Ferguson, and generally within the range reported by Ritchie (1971).

Raw Material: 1 quartz, 1 rhyolite

Description: These Brewerton ear-notched points are characterized by trianguloid blades, small side-notches, and concave bases that have flaked "ears" on either end. The Kettering Park Site sample consists of two complete projectile points. Both of the specimens had blades with one concave side and one convex side. The rhyolite point was crudely flaked and asymmetrical, and had a thinning failure in the form of a large hump on one face. The quartz point had a serious material flaw that ran up about 80% of the blade and parallel to the adjacent side. On both examples the basal ears were asymmetrical: the rhyolite point had both a thick and a thin ear, and the quartz point exhibited one basal ear longer than the other. The base and stem of the quartz point had been ground slightly, and its base thinned.

Chronology: Ritchie (1971) dates this form to both the Middle and Late Archaic (6500 B.C.-1000 B.C.). He states that the ear-notched point is a minority type in the Brewerton assemblage (less than 8% of the total) (Ritchie 1971:22). Gleach (1987) assigns this type to the Late Archaic, which he dates to between 3700 and 2000 B.C.

Comparative Data: Ritchie (1971) provides the following size ranges for Brewerton ear-notched points: length ranging from 18-61 mms (most measure 24-37 mms; mean=39 mms); the maximum thickness ranges from 5-8 mms with a mode of 6 mms. Kinsey reported on a sample size of 10, with lengths ranging from 29-55 mms (mean=42), and widths ranging from
Source: Engineering-Science

Kettering Park Site

Figure 13
Brewerton
Ear-Notched Points
19-29 mms (mean=25). Brewerton ear-notched points have been reported for the lower Delaware Valley (Kinsey 1972), eastern New York, and southern New England (Ritchie 1971). The two specimens from the Kettering Park Site were on the high end of Kinsey's range.

* Measurement of incomplete specimen
Kettering Park Site

Raw Material: 2 quartzite

Description: The Dry Brook Fishtail projectile point was missing its tip, had a bevelled blade (due to resharpening), and a ground base, and had several hinge fractures located on the blade, neck, and base. This projectile point also showed evidence of thinning failure, as well as a margin spall, and grinding on both its base and stem. The Orient Fishtail point lacked a basal corner and exhibited a heavily bevelled blade due to resharpening.

Chronology: Gleach (1987) has dated this point from the Late Archaic to Early Woodland (2100-800 B.C.). Ritchie (1959) reported dates at the type site at Stony Brook as late as 763 B.C. ± 220. Fishtail points have been found in association with steatite vessels and occasionally with early pottery (Kinsey 1972).

Comparative Data: These two fishtail types are the only forms that have been recognized, and are roughly similar in geographic distribution and time span (Ritchie 1959). The main morphological distinction between the variants appears to be a slightly wider and more prominent shoulder associated with the Dry Brook type (Kinsey 1972).

Ritchie’s sample of 71 Orient Fishtails measured 37.3-101.6 mms in length (mean=53.2), 17.5-30.3 mms in width (mean=19.1), and 6.4-7.1 mms in thickness. A sample reported by Kinsey (1972) ranged from 41-71 mms in length (mean=50), 14-28 mms in width (mean=20), and 6-9 mms in thickness (mean=7). Dry Brook measurements were almost identical, with widths averaging slightly greater (Kinsey 1972). A Fishtail variant was defined among a small sample from Henrico County in central Virginia (Gleach 1985), with lengths ranging from 29-72 mms (mean=52.3), widths from 19-29 mms (mean=23), thickness 8-12 mms (mean=9.7). The Orient Fishtail from the Kettering Park Site falls exactly within the range described by Kinsey, and the Dry Brook Fishtail is slightly smaller than the mean described by Gleach.

Raw Material: quartz (n=1)

Description: This point was asymmetrical due to extensive blade resharpening. One blade edge had been resharpened more frequently leaving an elongated edge that crossed the original median line of the projectile point. This resharpened edge was still sharp, and its shape indicates that it may have last been used as a knife. The point's straight stem appeared to be
Kettering Park Site

broken, and the break left a canted base. The body was thick and had several hinge fractures. The apparent breakage of the base prohibits an absolute type attribution.

Chronology: This point is dated to the Late Archaic (3400-2500 B.C.) in northeastern sites (Ritchie 1971; Kinsey 1972) and from 2600-1600 B.C. for Virginia (Gleich 1987).

Comparative Data: The type site for the Lamoka point lies in west-central New York. The geographic distribution of the type is centered there, though it is reported throughout the Middle Atlantic (Inashima 1989; Hranicky 1991). Most reported dimensional ranges are: 27-34 mms in length (mean=34), 14-28 mms in width (mean=17), and 4-8 mms in thickness (mean=6) for certain Pennsylvania examples (Kinsey 1972); 25-63 mms in length and 6 mms in thickness for the New York examples (Ritchie 1971). The specimens from southwest Virginia range from 28-34 mms in length (mean=31), 15-24 mms in width (mean=19), 8-16 mms (mean=11) in stem length, and 4-8 mms (mean=6) in thickness (Gleich 1985).

Raw Material: 1 quartz, 1 rhyolite

Description: This point type generally had a triangular blade with straight to convex sides, with an expanding stem and a concave base with "acute and prominent" tangs (Ritchie 1971:53). The two specimens of this type recovered from the Kettering Park Site are incomplete; both were distal ends, had thinned bases, and ground stems and bases. The quartz projectile point displayed a margin spall along a material flaw; the breakage of the point may
Source: Engineering-Science

Kettering Park Site

Figure 16
Susquehanna
Broadspear Points
have been caused by a massive impact fracture. The rhyolite point had a clean snap at about the mid-blade and was badly weathered.

Chronology: Ritchie (1971:53) dates the Susquehanna Broadspear point to the transition between the Late Archaic and Early Woodland Periods 1200-700 B.C. He specifies that this type is poorly understood because most known examples are surface finds. This point type is typically found in the Susquehanna River Valley in Pennsylvania and New York, as well as in the Delaware Water Gap, along the Seneca River and its tributaries, the Mohawk and Hudson Valleys, Oneida Lake, and in the Finger Lakes region.

Comparative Data: New York examples range from 36-75 mms in length (mean=55.5), but examples that are as long as 196 mms also have been reported occasionally. The thickness of these New York examples ranged from 4.6-9 mms (mean=6.8) (Ritchie 1971). The projected lengths for the examples from the Kettering Park Site are smaller and on the lowest end of the size range provided by Ritchie.

Raw Material: quartz (n=2)

Description: These projectile points had long, triangular blades and short straight stems; one was very weakly shouldered and had a convex base, and the other had a straight base. Both specimens had finished bases that were not thinned. These examples are very similar to the Holmes type discussed below.

Chronology: This point type is dated to the Late Archaic. Holmes points were recovered in association with the small variant Savannah River type at Plum Nelly, in Tidewater Virginia, in deposits radiocarbon dated to 2155 B.C. ± 95 (Potter 1982). A date of 1550 ± 150 was obtained at White Oak Point in Westmoreland County, Virginia (Waselkov 1982).

Comparative Data: There are no large samples of Holmes points, and there are no data on the size ranges. There is some overlap in morphology between these stemmed points and the Bare Island type as it was defined by Kinsey (1959). The time ranges between Holmes and Bare Island are similar enough for the difference to be of little consequence here. The points from the Kettering Park Site, though untyped, are very closely related to the Holmes type, and as such the possible time differences are also inconsequential.

* Measurement of Incomplete Specimen

Raw Material: quartz (n=1)

Description: This specimen was a stemmed point that had a triangular, straight-sided blade. Only one side of the stem remained; it was contracting and slightly incurring due to resharpening. The tip appeared to have been broken off by an impact fracture. Frequent resharpening left the point asymmetrical and the edges very sharp. One basal corner was missing, due to breakage along a material flaw.
Kettering Park Site

Chronology: This point dates to the Early Woodland. Radiocarbon dated from 1200 to 1000 B.C. at White Oak Point in Tidewater Virginia (Waselkov 1982).

Comparative Data: The largest single assemblage of Calvert points resulted from excavations at the type site of Accokeek Creek south of Washington, D.C. (Stephenson and Ferguson 1963). These points ranged in length from 25-48 mms (mean=36), and in width from 18-27 mms (mean=22). The specimen from the Kettering Park Site (18PR174) fell near the mean for that assemblage.

* Measurement of Incomplete Specimen

Raw Materials: quartz (n=7), rhyolite (n=1)

Description: All specimens were roughly lozenge shaped, with long blades that had straight to slightly concave edges, and a short stem. All of the points exhibited basal thinning, but only one had a ground base. Five of the points had contracting rounded bases and three had contracting pointed bases. Four points were complete and four were incomplete: three had their tips broken off (two were due to impact fractures), and one lacked at least a third of its blade and had damage to one shoulder. All of the incomplete examples were made of quartz. Three of the quartz specimens had resharpened blades, and two had shoulders that were slightly more rounded compared to classic examples. The remaining specimens displayed the more angular shoulders characteristic of this projectile point type.

The rhyolite projectile point was clearly a manufacturing reject; a large asymmetrical spall was missing on one face, and a portion of residual weathered surface on the other face that indicates that this piece probably was a reworked older point that showed signs of use wear on the tip.
Source: Engineering-Science

Kettering Park Site

Figure 19
Piscataway Points
Chronology: The point type dates to the Early to Middle Woodland, possibly originating in the latter portions of the Late Archaic. Dated by association to 1000 to 500 B.C. in southern Virginia (Mouer et al. 1981). Lack of absolute dates associated with Piscataway points had led to several wide-ranging chronological assessments for this type. For example, they have been reported in presumed Late Archaic levels at Rupert Island off the Maryland shore of the Potomac (McNutt and Gardner n.d.; Evans 1984), and below a component referred to as Vernon, radiocarbon dated to 3150 B.C. at the Fraser site, also located on the lower Potomac (McDowell 1972). Based on these data, Steponaitis placed Piscataway in her Late Archaic I sub-phase (4000 to 3000 B.C.) along the Patuxent River. Johnson’s (1985) survey of Piscataway chronology suggested that manufacture of this type may have extended well into the Middle Woodland. A total of 310 Piscataway projectile points were recovered at the Accokeek Creek site. These points were dated to the Potomac Creek component of the Late Woodland Period (Stephenson and Ferguson 1963).

Comparative Data: Piscataway projectile points reported from the type site on Accokeek Creek ranged in length from 29-49 mms (mean=37), in width from 10-21 mms (mean=14), and in thickness from 5-10 mms (mean=7) (Stephenson and Ferguson 1963). The specimens from the Kettering Park Site were all close to means reported by Stephenson and Ferguson.

* Measurement of incomplete specimen

Raw Material: rhyolite (n=1)

Description: This projectile point typically has a triangular blade and a short, straight stem with a straight base. The Potts corner-notched point recovered from the Kettering Park Site was a nearly complete point with a distal break, a finished base that was not thinned, and ground stem sides. It also was heavily weathered.
Chronology: Hranicky (1991:46) dates this projectile point type to 0-200 A.D. in Virginia. Gleach (1987:94) dates the use of this projectile point type to between 100 B.C and 400 A.D. There are no absolute dates for this point type, but it had been dated to the Early Woodland Period based on its associations.

Comparative Data: Gleach’s (1987:94) sample size was 26 points from the Virginia Commonwealth University collection. They ranged from 20-46 mms in length (mean = 34.5, std. dev. = 8.6 mms), 17-30 mms in width (mean = 22.2, std. dev. = 3.2 mms), 4-10 mms in thickness (mean = 6.5; std. dev. = 1.3 mms) and their length-to-width ratio ranged from 1.05-2.21 (mean 1.67; std. dev. = 0.33). The single Potts corner-notched point from the Kettering Park Site was within the Gleach’s size range, tending towards the lower end of the scale.

* Measurement of incomplete specimen

Raw Material: 3 quartz, 1 quartzite

Description: These points are typically thick, short, and wide, with a constricted stem and an expanding, straight base (Stephenson and Ferguson 1963). The four examples of this type from the Kettering Park Site generally conformed to this description, except one quartz projectile points that had a slightly concave base due to reworking. The quartzite point was complete, and the three quartz points were nearly so. One lacked a very small fraction of its tip, another was missing a small fraction of its shoulder, and the third was missing a fragment of one of its basal corners. One of the quartz points was made of a yellow and white diagonally veined quartz, and had a steeply bevelled blade. Another of the quartz points was asymmetrical due to a fracture along a material flaw that removed its shoulder; the shoulderless edge was then
Kettering Park Site

resharpened. All of the specimens exhibited asymmetrical blade edges. One of the quartz points displayed grinding only at the junction of its neck and shoulder, another showed a ground base, and the last had grinding on its base and stem. All the specimens had unthinned finished bases.

Chronology: Vernon points were originally identified at the Accokeek Creek site (Stephenson and Ferguson 1963). The Vernon point is a poorly understood type, being identified only sporadically in the literature; dating is vague or questionable. The Vernon type is also often confused and/or lumped together with the Halifax type, often under the hybrid name of Halifax/Vernon (e.g., Johnson 1986; LeeDecker et al. 1991), and given dates ranging from Halifax-like late Middle Archaic through to the Early and Middle Woodland Periods. Stephenson and Ferguson (1963) placed the Vernon type in the Early Woodland base on relative associations with Calvert points and Marcy Creek ceramics.

In contrast, Vernon points were reported stratigraphically below Holmes points at Ruppert Island (McNott and Gardner n.d.; Handsman and McNott 1974; Evans 1984). Side-notched points reported as resembling Vernon were radiocarbon dated to approximately 3000 B.C. at the Jeffrey Rockshelter in southwestern Virginia (Johnson 1968), yet the points may in fact have been Halifax. The Vernon type was absent from Wright’s (1973) chronology of the central Chesapeake area. Steponaitis’ (1980) survey of the Patuxent River drainage placed Vernon in the Late Archaic II sub-phase (3000-2200 B.C.) contemporaneous with both the Halifax and Brewerton types. In her chronology, the Calvert type was diagnostic of the Early Woodland Period, and was believed to be associated with Accokeek Creek ceramics.

The Neha site (44FX1561) in Fairfax County produced the nearest to an absolute date known for side-notched points. A radiocarbon assay of 510 ± 90 B.C. was obtained from a pit feature at the site, associated with Vernon and Piscataway points as well as sandstone-tempered ceramics and a St. Albans point, the latter suspected of being scavenged and recycled (Moore 1990, 1992). Thus it appears that Stephenson and Ferguson’s original chronological placement of the Vernon type may have been reasonably accurate.

Comparative Data: Stephenson and Ferguson (1963) reported a sample of 423 Vernon point with dimensions of 24-49 mms in length (mean=37), 16-30 mms in width (mean=23), and 6-13 mms in thickness (mean=10). The Vernon specimens from the Kettering Park Site fall within the range reported by Stephenson and Ferguson.

* Measurement of incomplete specimen

Raw Material: quartz (n = 1)

Description: This specimen was a quartz projectile point missing its tip and one of its basal corners. The blade was bevelled due to resharpening, the base was concave, and the remnants of the sides were straight. Both its base and notches were ground.

Chronology: This point probably dates to the late Middle or early Late Archaic. This untyped point appears to be related to the Halifax type. Halifax points are confidently dated to the late Middle or the early Late Archaic (Johnson 1986).

* Length estimated from existing lines

Raw Material: dark yellow/mustard Jasper (n=1), quartz (n=4), quartzite (n=3)
Description: These are typically thin, relatively symmetrical points roughly in the shape of isosceles triangles. Blade edges were straight \((n=3)\), slightly concave \((n=1)\), and slightly convex \((n=4)\). Five of the recovered points had thinned bases. Only two of the examples were complete; two had evidence of impact fractures; one exhibited a distal reverse hinge fracture; one had a distal fracture due to an undetermined error; one was a margin spall; and one was a distal fragment. Two of the quartz projectile points may have been manufactured by the reworking of an older point. The jasper specimen had lightly serrated edges and was markedly asymmetrical.

Chronology: This point type dates to the Late Woodland, 900 to 1350 A.D. The type is reported to have first occurred around 700 A.D. in New York state, but it was not commonly manufactured until 900 A.D. This projectile point type was gradually replaced by smaller, straight-based types, such as Madison, by the mid-fourteenth century (Ritchie 1971).

Comparative data: A sample of 250 Levanna points had been reported by Ritchie. Their lengths ranged from 22-76 mms (with most measuring between 32 and 45 mms), widths ranged from 21-35 mms, and the thickness averaged 5 mms (Ritchie 1971). Kinsey reported examples from the Upper Delaware Valley with lengths ranging from 18-45 mms (mean=34), widths from 18-34 mms (mean=22), and thicknesses from 3-5 mms (mean =4) (Kinsey 1972). The present specimens had a length range of 20-31 mms with a mean of 25.2 mms, below the means provided by Kinsey. The widths of the present specimens range from 21-28 mms with a mean of 24.8, slightly larger than Kinsey’s mean and well within the range provided by Ritchie.

* Measurement of incomplete specimen

Raw Material: rhyolite
Kettering Park Site

Description: This small triangular point exhibited a straight base, one slightly convex blade edge, and one slightly concave blade edge. A break was evident on the remaining distal end, probably due to a flaw in the material.

Chronology: This point type dates to the Late Woodland (800 to 1650 A.D.). This projectile point type was originally referred to as the Mississippi Triangular by Scully (in Ritchie 1971), who later renamed the point as Madison. This type is similar to Caraway projectile points, dated to 1700 A.D. at the Doerschuk site in North Carolina (Coe 1964).

Comparative Data: Scully’s original points were reported as measuring 13 to 60 mms (mean=25). Ritchie (1971) described a sample of 100 Madison points from an Iroquois site in New York with lengths ranging from 19 to 40 mms, widths from 13-27 mms, and thicknesses averaging 3 mms. Kinsey (1972) reported examples of Madison points from the Upper Delaware Valley with lengths ranging from 25-45 mms (mean=35), widths from 24-36 mms (mean=29), and thicknesses from 5-8 mms (mean=6). Coe’s (1964) Caraway points, by comparison, were reportedly 20-30 mms in length. The present specimen is small in comparison to the dimensions reported by Scully, Kinsey, and it is on the small end of the range reported by Ritchie.

Projectile Point Fragments (n=16)

Because of their fragmentary nature, the majority of the point fragments recovered at the Kettering Park Site were temporally unclassifiable types. The point fragments were made from five raw material types, although most were from quartz and quartzite (Table 7). Four of the 16 projectile point fragments, however, had attributes that suggested a temporal assignment. One of the points was identified as an Early Archaic point, and three others were identified as Late Archaic forms. The Early Archaic point was a distal fragment, made of quartz, and had two serrated blade edges. The three Late Archaic points were made of quartz, quartzite, and rhyolite.

**Bifaces**

This section discusses non-projectile point bifaces. Traditionally bifaces are classified according to their stage of manufacture. Ebright (1992:111) has stated, "Non-specifically shaped bifaces may represent blanks for specific bifacial tools, or may have functioned as finished tools without further modification." Ebright further states that there may be functions associated with each stage throughout the tool’s use-life. The classification below is based on Ebright’s slight modification of the terms as they were defined by Callahan (1979) (his Stage 1 is omitted thus Stage 1 here is equivalent to his Stage 2). Stage 1 is the initial edging stage. Stage 2 is the primary thinning stage, and Stage 3 is secondary thinning.
82 Kettering Park Site

**Stage 1 Bifaces** (n=10) (Figure 24)

Ten of the 17 classifiable bifaces were Stage 1 bifaces. The raw materials were six quartz, three quartzite, and one rhyolite. Of these, six had thinning failures, two had perverse fractures, and two had material flaws. The high percentage of thinning failure (60%) can clearly be seen in the low width/thickness ratios. All of the bifaces with thinning failure errors had a width/thickness ratio that clustered around 2.0, and a third of these (n=2) were between 1.5 and 2.0. Half (n=5) of the Stage 1 biface specimens in this collection contained remnant cortex: one of these had cortical remains on both its base and tip, two others were made on bipolar flakes or cores. All were made of quartz. One of the quartz Stage 1 bifaces may have been an exhausted core. One of the quartzite bifaces appeared to be narrow-bladed. The rhyolite Stage 1 biface appeared to be a large quarry blank; it bore evidence of thinning failure and a perverse fracture, the latter possibly resulting from attempts to remove stacks.

**Stage 2 Bifaces** (n=6) (Figure 24)

The Stage 2 bifaces consisted of three quartz and three quartzite specimens. The width/thickness ratios for quartzite bifaces were slightly higher than for the quartz ones. This indicates greater success in thinning quartzite, which may in turn suggest variation in the knapping characteristics of the two lithic materials. Of the three quartz bifaces, two had thinning failures and one had a margin spall. One of the quartz bifaces had a large knot on one edge and a tip that appears to have been utilized; the second was crudely flaked and asymmetrical; and the third was plano-convex in cross-section. Each of the three quartzite Stage 2 bifaces had different combinations of manufacturing errors: one had end shock; another had a material flaw, a perverse fracture, and thinning failure; and the third had both a perverse fracture and thinning failure. One of these quartzite bifaces had a possible area of polish on one end. Two of the bifaces were trianguloid, and four were ovoid.
Source: Engineering-Science

Kettering Park Site

Figure 24
Stage 1 and
Stage 2 Bifaces
Stage 3 Biface (n=1) (Figure 25)

Figure 25: Stage 3 Biface

The Stage 3 quartzite biface appears to have been used as a bipolar core after biface reduction. It had some unusual flake scarring, indicating that it was struck from the side and a large traverse flake was removed. This piece was a proximal fragment; its distal edge bore evidence of a perverse fracture. Its base was canted.

Unclassifiable Biface Fragments (n=27)

In total, 27 unidentifiable bifaces were recovered from the Kettering Park Site. Six of these may have been projectile point segments, but they were too fragmentary to state their original form with certainty. In total, 6 fragments were from undetermined parts of a biface, 4 were tip fragments, 5 were base fragments, 2 were mid-section fragments, and the remaining 10 were lateral fragments. Four of the total sample (14.8%) had remnant cortex: three had cortex on one face, and the other had cortex on one end. One of the quartz specimens may have been a bipolar core fragment, possibly used as a scraper. One of the chert specimens was possibly used as a graver.

The primary cause of breakage among the bifaces was material flaws (n=10, 37%). Other bifaces in this group showed evidence of perverse fracture (n=3), reverse hinge fracture
Kettering Park Site

(n=2), margin spalls (n=2), a combination of perverse fracture and thinning failure (n=1), and a combination of material flaw, thinning failure and reverse hinge fracture (n=1). Eight (29.6%) of the bifaces had breaks of undetermined origin.

Unifacial Tools

A total of 34 unifacial tools was recovered. A list of uniface measurements appears in Appendix G. Among the unifacial tools were a graver, end scrapers, a side scraper, unclassified scrapers, and retoucheddebitage.

Graver (n=1) (Figure 26)

Figure 26: Graver

A single graver was recovered from the Kettering Park Site. It was made on a quartz decortication flake in an elongated oval shape. One of the sides of the specimen was finely retouched and one of the ends had four graver spurs. The specimen's width/thickness ratio was 4.2.

End Scrapers (n=3)

All three of the end scrapers recovered from the Kettering Park Site were complete, made of quartz, and contained remnant cortex. One of these tools appears to have been made on a recycled broken hammerstone; a portion of the cortical surface had an area of heavy battering.
This tool was trianguloid in shape. The remaining end scrapers were made on bipolar pebbles and were both oval in shape. The end scrapers ranged in edge angle from between 62 and 78 degrees. Edge angles displayed very little variation, which may imply either that utilization was similar for most of the examples, or that edge angle was not a critical index of use.

*Side Scraper* (n=1) (Figure 27)

![Figure 27: Side Scraper](#389.001)

The side scraper was made from a large chert decortication flake. One side was finely retouched and its bit end was straight with two small flakes removed. The edge angle, overall shape, and flake pattern suggest that this specimen was probably used as a knife. This tool was considerably larger than the end scrapers found at the site, and its edge angle was considerably smaller.

*Unclassified Scraper Fragments* (n=2)

One of the unclassified scraper fragments was made of quartz and had two possible working edges, one convex and the other concave; it is also possible that it may be a core fragment. The other scraper fragment was made on a cobble spall; cortex covered its flat edge.
87 Kettering Park Site

Retouched Debitage

All of these artifacts were included in the retouched category since they had evidence for unifacial working. The retouched debitage consisted of 21 retouched flakes, 2 chunks, and 4 cores. Most of the retouched debitage were made from chert and quartz (Table 8).

Cores

A total of 130 cores was recovered from the Kettering Park Site. A list of core measurements appears in Appendix H. The cores consist of bipolar cores, multifacial flake cores, and unclassifiable core fragments (Table 9, Figure 28). The following discussion is organized by core type. As appropriate, attributions of morphology, exhaustion, platform pairs, and raw material type were examined.

Source: Engineering-Science
Multifacial Flake Cores: Multifacial flake cores were made of quartz, chert, and quartzite (Figure 29). The weight of the quartz cores of this type ranged from 11-50 gms (mean = 27.70; std. dev. = 12.36; coef. var. = 0.54), and the maximum length ranged from 33-51 mms (mean = 39.90; std. dev. = 5.82; coef. var. = 0.150). The maximum width of these cores ranged from 19-34 mms (mean = 29.00; std. dev. = 4.8; coef. var. = 0.17), and the maximum thickness ranged from 12-24 mms (mean = 17.7; std. dev. = 3.63; coef. var. = 0.21). The single quartzite core recovered weighed 50 gms, had a maximum length of 48 mms, a maximum width of 40 mms, and a maximum thickness of 23 mms. The two chert cores were markedly larger than any other material type: they weighed 82 and 126 gms, measured 65 and 70 mms in maximum length, 39 and 52 mms in maximum width, and 45 and 33 mms in maximum thickness, respectively. Remnant cortex was absent on five (38.5%) of the multifacial flake cores in this collection. Of the remaining eight specimens, one core (7.7%) had bedding plane or tabular cortex, and the other seven (53.8%) had pebble or cobble cortex.

Kettering Park Site (18PR174)
Bipolar Cores: The largest quantity of cores were classified as bipolar cores (Figure 30). Most of the bipolar cores were made of quartz (n=84). The maximum length of quartz bipolar cores ranged from 9-74 mms (mean=26.88; std. dev.=8.99; coef. var.=0.33), maximum width ranged from 7-41 mms (mean=20.68; std. dev.=6.93; coef. var.=0.34), and the maximum thickness ranged from 4-29 mms (mean=11.60; std. dev.=4.56; coef. var.=0.39).

The next most frequently recovered material utilized in bipolar technology was quartzite (n=10). These cores ranged in weight from 2-33 gms (mean=10.20; std. dev.=8.83; coef. var.=0.87), in length from 14-45 mms (mean=32.2; std. dev. 12.63; coef. var.=20.39), and in maximum width from 12-34 mms (mean=20.9; std. dev. 6.27; coef. var.=0.30). The maximum thickness of quartzite cores ranged from 7-24 mms (mean=12.6; std. dev.=4.8; coef. var.=0.38).

Most of the bipolar cores had one set of platform pairs (n=44, 46%) indicating that the cores had been struck along a single axis. Of these cores, 38 were quartz, 1 was chert, 4 were quartzite, and 1 was of an undetermined igneous material. A total of 39 bipolar cores (40.6%) had two platform pairs, indicating flaking along two, often perpendicular axes; 35 were quartz, 4 were quartzite. Ten quartz core and one quartzite core each had three platform pairs (11.5%), and one quartz and one quartzite artifact each had four platform pairs (2.1%).

Cortex was absent on 31 of the bipolar cores. Of these, 29 were quartz, 1 was chert, and the other was quartzite. Four of the remaining bipolar cores had bedding plane or tabular remnant cortex, and the other 61 had remnant cortex of the pebble or cobble type.

Bipolar reduction had been cited as typical of cobble/core technology (Stewart 1987), the hammer and anvil technique being the easiest for setting up platforms on small, rounded pieces. Most of the cores and core fragments from the Kettering Park Site were in fact, small, apparently derived from secondary deposits of quartz and quartzite in the nearby stream, and most bore cobble cortex.

There were few prepared cores in the collection from the site. Most consisted of what have been referred to as expedient cores (Stewart 1987), in which irregularly shaped flakes were struck for immediate and short-term use. Expedient core/flake production is often associated with proximity to lithic sources. Easy access to a large amount of raw material in local stream beds suggests that this pattern was valid at the Kettering Park Site. Further indication of this quick and relatively efficient production of flake tools is seen in the high frequency of multiple
bipolar platform pairs, suggesting that bipolar flaking was not used solely to split pebbles and cobbles, but also to reduce cores, in some cases, to exhaustion. The small sizes of the initial pebbles, producing small cores, may have also dictated the use of bipolar flaking for continued reduction.

**Lithic Debitage**

Lithic debitage, with the exception of cores, was summarized in Table 2. In order of number represented, the highest debitage types were secondary flakes (n=1259), lithic chunks (n=1244), decortication flakes (n=583), primary flakes (n=475), and tertiary flakes (n=388). The lithic debitage was summarized by material type (Figure 31). Quartz was the most commonly found material followed by quartzite, chert, and rhyolite in declining order of quantity. Four other types of raw material and an undetermined type was represented, but these made up only a small percentage of the total.

The lithic debitage for the four most commonly occurring raw materials (i.e., quartz, quartzite, chert, and rhyolite) was summarized by four morphological types (i.e., Decortication Flakes, Primary Flakes, Secondary Flakes, Tertiary Flakes) (Figure 32). The information indicated that all stages of manufacture were represented at the site, from the procurement of material to the final finishing. The summaries also indicated that some trends were expressed in the data. A high percentage of Decortication Flakes were made of quartz. Conversely, chert, rhyolite, and quartzite were better represented in the Secondary stage category. This trend is reflective of the fact that quartz was locally available, and may have been reduced on the spot, whereas chert and rhyolite was procured from more distant sources, and therefore consisted of higher percentages of reduced material. This information appears to be a potential indicator of the distance and accessibility (whether through trade or travel) of the sources of the lithic materials recovered at the site.

*Ground Stone and Use Modified Tools*

A full list of ground stone and use modified measurements appears in Appendix 1. Two ground stone implements were recovered at the Kettering Park Site. The first was a very small soapstone bowl fragment. The second was a fragment of a siltstone bannerstone (Figure 33). The bannerstone fragment was well made, and had a polished surface and a drilled hole.

Eight lithics classified as use modified stone tools were recovered at the site. All of these were possible edge-battered hammerstones. The total weight of these artifacts was 738 gms (mean = 67.09). Of these, four were made of sandstone, and three were made of quartzite, and one was made of greenstone. Four of the sandstone tools were pebbles with roughened surfaces, another was elongated and possibly functioned as a pestle, and another had pronounced battering on one end, and lighter battering on the other side.

*Figure 33: Bannerstone Fragment*
Summary

Excavations at the Kettering Park Site provided evidence of prehistoric occupation from the Early Archaic through the Late Woodland Periods. Based on the quantity of diagnostic material, the most extensive use of the site occurred during the Late Archaic/Early Woodland Period and the second largest occupation was during the Late Woodland Period. While there were Early and Middle Archaic artifacts, the material evidence was minimal. Artifacts dating to the Middle Woodland Period were limited to 11 ceramic fragments, which probably indicates a minimal usage of the site during that time.

The abundance of cores, both bipolar and multifacial flake types, and other lithic debitage (e.g., Lithic Chunks, Decortication Falkes, Primary Flakes, Secondary flakes), suggested that substantial lithic tool manufacture occurred at the site. Although no features were located, the relative abundance of Early Woodland and Late Woodland Period ceramics indicates that the site may have functioned as a semi-sedentary locale.
VIII. RESIDUE ANALYSIS

Camille Juliana used the Chemstrip Test Method to determine the presence or absence of hemoglobin on 10 lithic artifacts recovered during the Phase II testing at the Kettering Park Site. Five projectile points and five non-point artifacts were selected to test a range of lithic artifact types for possible residue. The main criterion for tool selection was the presence of use-related minor breakage. This criterion eliminated the possibility that the tools selected, for whatever reason, had not been utilized (thereby not having been exposed to tissue and blood).

Methodology

The following is Camille Juliana’s description of the methodology she employed for the blood residue analysis.

The artifacts are soaked individually in vials in water solutions. The hemoglobin, as a salt, dissolves into this solution. The solutions are tested after the first and third days, with color-changing paper coated plastic strips sensitive to the presence of hemoglobin. Even minute traces of hemoglobin, if present, will be indicated by a slight change of color.

The second phase of the technique is to put any remaining hemoglobin into solution. This involves subjecting each vial to a sonic vibrator, which agitates the solution and frees the tool of any remaining residue. Of course, all sediment is suspended in solution as well, which produces a false positive reaction, presumably due to the interfering actions of fine particulates such as clay. Therefore, to eliminate the suspended sediment, it is allowed to settle out for two weeks, then the remaining clear solution is tested. The purpose of this phase is to maximize potential hemoglobin by removing all of it from the tool surfaces and placing it into solution. Additionally, it allows the tool to be removed, cleaned, and available for further analysis.

It was reported that the presence of contaminant, particularly manganese oxide, in the soil matrix could contaminate the results and register a "false positive" (Custer et al. 1988:100). Samples from the Kettering Park Site were tested, and manganese oxide contamination was absent. Consequently the following results for the presence of blood residues on 10 lithic artifacts from the Kettering Park Site are believed to be reliable.
98 Kettering Park Site

Results

Of the 10 artifacts tested, only 1 (or 10%) showed a positive result; 7 were negative (70%), and 2 were possible (20%). A Piscataway projectile point with a chipped tip tested positive; all other projectile points tested negative. Only flakes tested possible for the presence of blood residues; the remaining lithic artifacts tested negative. According to Juliana the results of "probable" and "possible" reflect weak positive reactions that were verified through repeated testing of the solution."

These results indicate that it is probable that both formal and expedient tools were used for killing and butchering animals at the Kettering Park Site. Given the small sample and the fact that only one of the objects tested positive, these results are to be considered preliminary. No further testing for blood residue were conducted for either Phase II or Phase III lithics recovered because this study was mostly an experiment with use of the technique. It was the first of its type undertaken by the State Highway Administration. Among its primary goal was to determine whether the analysis of blood residues was a fruitful research endeavor. Juliana felt that the results indicated that blood residue analysis had potential as an analytical tool.
IX. SITE INTEGRITY AND SPATIAL ANALYSES

Site Integrity

As the excavation profiles indicated three main horizons were identified: 1) an uppermost A1 horizon, consisting of a humus and a mix of plowzone and alluvial and sheetwash deposits; 2) an A2 horizon, which consisted of subplowzone deposits, and inferred to be relatively intact; and 3) a lowermost, ancient B horizon, which did not contain artifacts (see Chapter V, "Pedology and Stratigraphy"). To further document the stratigraphic information and support interpretations about depositional disturbance and integrity, temporally diagnostic projectile points and ceramics were summarized by excavation unit and horizon (Table 10). Table 10 demonstrates that certain information could be derived by examining temporal diagnostics by horizon.

The plowzone and sheetwash layer, or the A1 horizon, clearly contained an undifferentiated mixture of Archaic and Woodland materials, indicative of postdepositional alteration. The A1 horizon may represent a mix of redeposited Archaic material and Woodland material upheaved from the underlying A2 horizon. The A1 horizon contained projectile points of the Middle Archaic (two Normanskill), the Late Archaic/Early Woodland (two Vernon, three Piscataway, one Calvert), and the Late Archaic (one Untyped Straight-Stemmed, one Bare Island). With the exception of the deeply lying Early Archaic projectile point fragment in N115/W105, Archaic projectile points were not found in the A2 horizon. This suggested the possibility that the Middle to Late Archaic artifacts may have been redeposited by alluvial or sheetwash processes. Derivation of the Middle to Late Archaic materials from underlying deposits is considered unlikely because of the inferred intact position of Woodland materials in the A2 horizon.

In addition to redeposited material, the A1 horizon appears to represent Woodland material upheaved by plowing from underlying deposits. Given that virtually all of the excavation units contained Accokeek sherds in the A1 and A2 horizons, it is probable that the original top of the Accokeek component was at a higher elevation than the current top of the A2 horizon. This inference is supported by the fact that the Late Woodland artifacts were confined to the A1 horizon.

While the A1 horizon represents a plowzone deposit, certain spatial patterns suggested remnants of activity zones remained. For example, a spatially delimited pattern of chert material
Kettering Park Site

was identified in the A1 horizon of Unit N115/W105. Identification of spatial patterns indicated areas of relative integrity, and suggested activity zones could be inferred.

Based on the stratigraphic profiles and the position of the temporal diagnostics, the A2 horizon is considered to be a relatively intact deposit. Indicative of vertical integrity, no historical materials were found in the A2 horizon. Moreover, except for a single possible Townsend sherd in N124/W110, no Late Woodland artifacts were found in the A2 horizon. The Early Archaic projectile point was located at the bottom of Unit N115/W104, at the interface between the A2 horizon and the sterile zone that marked the stratigraphic integrity of this unit. Diagnostic materials from the A2 horizon primarily consisted of Early Woodland ceramics and Late Archaic/Early Woodland projectile points. While the A2 horizon appears to be relatively intact, vertical, postdepositional intrusions were likely. Field observations suggested some degree of bioturbation, and potential mixture by burrowing animals and roots. Confirming these observations, a single Middle to Late Archaic Brewerton Ear-Notched point and a single Late Archaic Untyped Straight-Stemmed point was found in the A2 horizon.

Spatial Distributions

For distribution analyses, the materials recovered from the STPs from the test and excavated units were separated, and results compared within and between different artifact classes. Artifact clusters maps were produced using the Surfer software program. In order to provide accurate maps, the data from the STPs were mapped independently. The independent mapping was mandated because of the size disparity between the STPs and the test and excavated units, and the relative lack of stratigraphic controls within the STPs. As previously stated, the Phase III excavated units (measuring two-meters square) were excavated as four 1x1 m contiguous units. This field methodology provided a database that was compatible with the Phase II test units for the purposes of computer-generated mapping.

The absence of features at the site mandated developing a research strategy that would address basic questions of whether artifact patterning was apparent in the horizontal distribution of the data. Graphic images that displayed the data clustered by material and level were produced using Surfer. Spatial distribution maps were made of major artifact classes. The anticipated result was that spatial patterns, potentially indicative of activity areas, could be detected. The following sections provide descriptions of specific debitage maps, which indicate the location of quartz, quartzite, rhyolite, and chert debitage. The debitage category, as used here, includes all classes with the exception of cores and bipolar material. The following sections summarize the spatial distributions for ceramics, fire-cracked rock, and projectile points.

### Quartz Debitage

Quartz is the most common material found at the site. Figure 34 shows the quartz
debitage distribution from the STPs, and Figure 35 shows the quartz debitage distribution from
the excavated units. Figure 34 identifies the density of quartz debitage in the northeastern area
of the block. The disparity between the peak areas present on Figure 34 and the excavations
displayed in Figure 35 indicates that the excavation was not geared towards the shovel tests with
the highest concentration of quartz debitage (in fact, excavations were geared towards the

Distribution from Units
ceramics recovery). Despite this fact, the distribution maps show that high concentrations of quartz debitage were found in excavated units. The data indicates that quartz tool manufacture was a relatively important and frequent activity in this location. The quartz debitage count in the plowzone totaled 926, and the sub-plowzone (A2 horizon) had 1628 pieces of quartz debitage. The greater number of flakes in the A2 horizon correlates with the generally higher quantity of most artifact classes in this stratum.

**Quartzite Debitage**

Quartzite was the second most commonly found lithic material at the site. In total, 998 pieces of quartzite debitage were recovered at the site; 821 of these were from the test and excavated units. A total of 504 fragments was from the A2 horizon, constituting 61.4% of the sample from the units. Although the presence of 60 pieces of debitage in N124/W110 was not evident from the STP results, all other areas of high quartzite debitage concentrations were consistent with the predicted results based on the STP data. The percentage of quartzite decortication flakes in relation to flakes produced by the later stages of manufacture indicates that quartzite may have been imported from non-local sources. The relative abundance of this material, compared to chert and rhyolite, suggests that its sources were located closer to the site, perhaps farther up one of the stream branches.

**Rhyolite Debitage**

The STP data on rhyolite debitage showed that it occurred in very small amounts over most site areas. Very small clusters appeared on the northern and western edges of the study area. It was also present in the northeast area, where N162/W138 was located, as well as on the site’s western edge. However, six was the largest number of flakes found in an STP. A larger number of flakes were found in both the test and excavation units, but 76 of these were from the plowzone (5.1% of the debitage recovered from the mixed A1 horizon) and 125 were from the A2 horizon (5.35% of the lithic debitage recovered) (Figures 36 and 37). Five of the seven rhyolite bifaces recovered from the A1 horizon were diagnostic projectile points that date from the Archaic to the Early Woodland Period (Figure 38). One of the remaining two bifaces was a Late Woodland Madison and the other was of questionable date. The highest concentrations of rhyolite debitage were located in the same units within which the Pre-Late Woodland Period diagnostic points were located. The highest concentration of debitage was always in the A2 horizon within these units. The areas where rhyolite was present in the A1
horizon generally appears more scattered, with an odd flake here or there when no early period diagnostic were present. This type of scattering may be attributed to postdepositional forces. The only unique concentration of rhyolite flakes in the A1 horizon occurred in N126.5/W120.5 where six flakes were located. In summary, the spatial analysis of the rhyolite debitage suggests that the presence of a relatively large sample of debitage in the A1 horizon may, to a great degree, be a product of postdepositional activities. The overall distribution of diagnostics and debitage indicates that the use of this material may have been more frequent during the Archaic and the Early Woodland Periods.

**Chert Debitage**

The A1 horizon contained the majority of the chert debitage, including 152 flakes and chunks (Figure 39). The A2 horizon only had 68 pieces, 44 of which were located in the level immediately below the plowzone (level 3 in all units). Upper level chert flakes cluster in the south central part of the study area. Cherts were examined by color and quantity. The most prevalent color was dark mustard yellow, and black cherts were the second most commonly found color. However, the quantities of black chert were too low to merit further spatial study.

Ceramics

The ceramic distribution from shovel tests was plotted, indicating a concentration in the southern and central parts of the site (Figure 40). Excavations in the A2 horizon indicate that ceramics were found in the southern and central portion of the site, but with increased density in the central area (Figure 41). Each of the three Woodland sub-periods had different vertical and horizontal ceramic distributions at the site. The highest concentration of Early Woodland ceramics were found at N132/W116 and N118/W112, N116/W108 and N110/W110 in the center of the main excavation block in the study area. This patterning does not appear to be a product of the sampling strategy, because ceramics were absent in many of the 1x1 and 2x2-meter units. The sample of Middle Woodland ceramics was very small and scattered. The only clear patterns were that these artifacts were found mainly in the plowzone and they were located exclusively in the largest excavation block in the study area. In contrast, Late Woodland diagnostics were found virtually exclusively in the plowzone and were clustered towards the southern and central-western sides of the largest excavation block within this stratum.

Fire-Cracked Rock

Fire-cracked rock distribution was plotted for both the A1 and A2 horizons (Figures 42 and 43). Examining this distribution determined whether remnant features could be identified. Furthermore, an attempt was made to examine whether the patterning of fire-cracked rock was similar to the ceramic spatial patterning. This correlation was studied as a means of determining possible cooking areas in the absence of hearth features. Fire-cracked rock was found in the A1 horizon of virtually every test and excavation unit. However, there appeared to be no meaningful correlation between the distribution of fire-cracked rock and ceramics in the upper strata of the site. The data from the A2 horizon were similar but the higher fire-cracked rock concentrations mirror the ceramic concentrations to a greater extent. However, N130/W96 was wholly devoid of ceramics but had 36 pieces of fire-cracked rock.

Projectile Points

The single Early Archaic projectile point and the three Middle Archaic points were all found on the central and southwestern sectors of the main excavation block (Figure 44). This sample is far too limited to draw conclusions about the earliest occupations at the site, rather than to say that it is possible that the southwestern side of the study area may have been the location of its earliest occupation.

Projectile points dating to the Late Archaic/Early Woodland Transition and to the Early Woodland Period were found in both excavation blocks, but they were concentrated in the central and southern areas of the largest excavation block in N87/W115, and in N126/W102, N118/W112, N118/W100, N112/W112, and N112/W108 (Figure 45). This distribution correlates well with the ceramic data, as well as the location of high concentrations of fire-cracked rock. The possible implications of these correlations will be discussed later.

Late Woodland projectile points were found in the central and southwestern areas of the site, but they do not cluster in any particular unit or in a large contiguous area (Figure 46). The small sample size limits the scope of possible conclusions. However, the combined data from STPs and the test and excavation units show that Late Woodland points are conspicuously absent from the northern zone of the study area, and that this generally conforms to the distribution pattern of the Late Woodland artifacts.

Projectile Point Distribution for the Late Woodland Period
Activity Areas

The debitage distributions showed clustering of materials, potentially indicative of activity areas. These spatial distributions suggested zones of potential stone tool manufacture (Figures 47-50). These zones were further investigated to assess potential functional associations and relationships.

Lithic Manufacturing Areas

The cluster in level 2 at N110/W110 suggested a chert-working area. This area contained 55 pieces of dark yellow mustard-colored chert in association with a retouched flake tool of the same material. This material was associated with 19 flakes of the same material that were reddened due to heat treating. The adjacent unit, N112/W112, contained six flakes of the dark yellow mustard-chert. A Levanna projectile point that may have been made from the same core (the color of the flakes in the concentration was variegated, and the point's material was within the range of colors present) was found on the surface during the Phase I survey at N119/W116.5. It was not directly associated with the activity area, however.

The spatial distributions indicate that the manufacture of quartz tools was conducted at the Kettering Park Site. Unit N142/W115, a 1x1-meter unit, contained a particularly high density of quartz artifacts, producing 708 flakes and 121 cores. All 2x2-meter units produced high densities of quartz flakes. A high concentration of quartz debitage was found in the A2 horizon (Figure 48).

Bipolar Manufacture

Distribution maps of bipolar cores and bipolar flakes were made to compare the distribution of these artifact types and to try to define activity areas. Bipolar technology was of particular interest because of the large quantity of cores recovered during the three phases of work at the site. The distribution of the bipolar flakes only clustered at one of the excavated units, N108/W98. This unit yielded the highest number of flakes (n=16) from a 2x2-meter unit, and it produced 6 bipolar cores. All of the bipolar cores and debitage were quartz, and only two fragments were recovered from above the A2 horizon.

The highest concentration of bipolar cores (n=11) recovered from a 1x1-meter unit was found at N142/W114 (Figure 47). Only a single bipolar flake was recovered from the same unit. All but one of the cores recovered were in level 3 or below, some were as deeply buried as level 6.

Kettering Park Site

Figure 48
Quartz Debitage
from the A2 Horizon
Kettering Park Site  125

The possibility that bipolar technology varied according to depositional context was tested. The percentage of bipolar debitage in relation to the total amount of debitage within the A1 and A2 horizons was calculated. The results showed debitage present in virtually equal percentages of the total lithic assemblage in the A1 (8%) and the A2 (7%) horizons. Similarly, 43 bipolar cores were found within the A1 horizon, and 36 were found below. While horizontal patterns appeared to be expressed, these data do not provide potentially useful technological information among horizons.

Other Possible Lithic Manufacturing Areas

The highest concentration of quartz manufacturing debris in the A1 horizon was located in N132/W116 (n=115). Twelve of the 115 flakes found were decortication flakes; however no cores were found in this unit. Furthermore, no cores were found in adjacent units despite the fact that in N134/W112, 18 of the 44 flakes recovered within a 2x2-meter square were decortication flakes. However 4 m south of Unit 1, in N130/W110, a total of 4 cores, 8 decortication flakes, and 33 pieces of debitage were found. This suggests that this general sector was a potential stone tool manufacturing area.

In addition, 19 other units (counting 2x2s as single unit) had concentrations of flakes associated with cores and cortical flakes. In fact, only unit N137/W101 contained only non-cortical material (n=5 flakes). Furthermore, 7 of the 19 units that contained cortical flakes also had cores. Table 11 presents the location and quantity of these three types of materials.

</tbody>
</table>
All but one of the units measured 2x2-meters; only N87/W115 measured 1.5 by 1.5 meters. This may indicate that 1x1-meter units with high debitage concentrations such as N132/W116 would yield cores if the excavation area were expanded. The associations presented in the above table suggests that there may have been several quartz-working areas. Moreover, these areas were present throughout the site with the highest concentrations located in the center of the large excavation block. Since most units contained flakes of all production stages, it is probable that the areas indicated by the above table were a product of the sampling technique. The low quantities of these materials in N126/W102 may indicate that the first stages of manufacture occurred in that location and the tool was finished elsewhere, or that plowing and other disturbances at the site displaced the additional debitage.

Previously it was stated that Unit N142/W115 was the location of the highest concentration of quartz debitage at the site. Of the 508 quartz fragments located there, 494 were quartz chunks (95.6%). A single multifacial flake core was found with 9 decortication flakes, 2 primary flakes, 10 secondary flakes, and 2 tertiary flakes. The small size of this core (maximum length was 34 mms, and maximum width was 32 mms) does not account for the large quantity of chunks found in this 1x1-meter unit.

All areas of the site that had more than 20, and less than 100 flakes, also contained both decortication flakes and cores. Areas of the site with very high concentrations of quartz debitage (over 100 pieces) tended to have high quantities of chunks, and no cortical material. The only exception to this pattern was at N135/W95 where, of a total of 135 pieces of debitage, only 9 were chunks. In total, 33 decortication flakes were found in this assemblage, and consequently the area appears to have been a tool manufacturing area. The distribution of the quartz debitage and associated cores clearly indicates that a great deal of tool manufacturing was carried out at this site. Table 12 quantifies the relationship between cores, decortication flakes, and other flake debris.

</table>

Several potential quartz-working areas associated with decortication flakes and cores were identified (Figures 49 and 50). The horizontal distribution of the activity areas is different, and they do not overlap. The vertical location of the potential activity areas are similar within the two horizons.

Two possible quartzite working areas in the A2 horizon were also detected. The areas contained a relatively high concentration of quartzite flakes, a few decortication flakes, and a core. The excavations at Unit N130/W110 revealed 3 decortication flakes, and 67 flakes produced during the later stages of manufacture (19 primary, 30 secondary, 13 tertiary, 3 unidentifiable flake fragments, and 2 chunks). It should be noted that level 2 immediately above this unit contained 76 flakes and 3 cores, but it was heavily disturbed by burrows and washes. It is likely that the disturbances carried this material upward because level 3 was relatively intact, but due to the quantity of disturbance it is difficult to state with certainty. The second area, Unit N130/W96, had 1 core, 3 decortication flakes, and 31 flakes pertaining to the later stages of manufacture (6 primary, 18 secondary, 8 tertiary, and 4 chunks). Given the low overall quantities of materials present in these areas, it appears that only part of an activity area was visible, and that the surrounding unexcavated areas could potentially contain more manufacturing materials.

**Comparative Artifact Distributions**

Among the activity areas that were identified were those associated with lithic production, which have high concentrations of discrete material types anddebitage. It should be noted that an attempt was made to determine which artifacts were made at the various activity areas. There
were no distinct correlations between the location of bifaces and lithic manufacturing areas, the only definite association found was the location of a chert unifacial tool in association with chert flakes. The provenience of the hammerstones recovered also did not correlate with the activity areas.

The overall artifact patterning at the site indicates an apparent inverse relationship between the location of manufacturing debitage and clusters of ceramic fragments. This inversion is particularly true of the A2 horizon, where the areas of highest lithic scatter tend to have the lowest quantity of ceramics (N142/W115 contained only one sherd). Although there were no features discovered at the site, the distribution pattern suggests a segregation of activities during the Early Woodland occupation, indicating that lithic reduction and food preparation and storage occurred in separate areas of the site. The highest concentration of ceramics was in the site center, and the lithic distributions clustered north and south of the N120 line.

X. GENERAL CONCLUSIONS

Synthesis

Archaeological evidence from the Kettering Park Site indicated intermittent site use beginning as early as the Early Archaic Period and extending into the Late Woodland. Evidence from the early portions of the Archaic was scant, consisting of the distal section of a projectile point with serrated blade edges judged to be Early Archaic, and four Middle Archaic points. The relative lack of material attributable to these periods suggests that site use was sporadic or ephemeral. More extensive site use occurred during the Late Archaic. Site use increased in the Early Woodland, during which period activity appeared to have been both complex and intensive. A limited amount of evidence of Middle Woodland occupation was recovered. The Late Woodland Period saw a resumption of activity, though at a less intensive level than in the earlier portion of the Woodland.

The horizontal extent of the site was defined by the current 21.5-22 m contour line. The western, southern, and eastern site limits are defined by the paleo-channels of the Northeastern and Western Branches, which are tributary drainages of the Patuxent River. The northern edge of the site is obscured by Maryland Route 214 and a sewer line north of the highway right-of-way. Nonetheless, sloping ground immediately north of the road probably represents the northernmost limit of site use.

The uppermost depositional unit, designated A1, appeared to have been a disturbed layer consisting of a complex of plowed and alluvial and sheetwash sediments. As discussed earlier, there is evidence that in some areas the lowest levels of the A1 horizon were relatively intact, yet it is apparent from the vertical distribution of artifacts in most units that the bulk of the materials from this time period were disturbed by tillage. Furthermore, although the A2 horizon was considered intact, there was probably postdepositional disturbance and intrusions of material from upper levels.

Chronology

A study of the Patuxent River drainage conducted by Steponaitis (1980) is one of the only comprehensive chronological surveys undertaken in the region, and is used here as a basis for the assessment of chronology at the Kettering Park Site (Table 13). The study consisted of a typological analysis of artifact collections from 89 sites in Anne Arundel, Prince George's, Calvert and St. Marys Counties, in southern Maryland. The resulting chronological sequence
was based on the presence of diagnostic lithic and ceramic artifacts dated at regional and often extra-regional locales. Table 13 summarizes the latter portion of the Patuxent River Survey chronology, beginning with the Late Archaic Period, during which occupation of the Kettering Park Site was most intensive. The list includes the characteristic artifacts used to define each subperiod, as well as corresponding diagnostic artifact types recovered at the Kettering Park Site and their frequencies of occurrence.

It should be noted that the Steponaitis's study was an appraisal of existing artifact collections, some of which were poorly documented or incomplete. The resulting chronology was based solely on changes in projectile point form and, for the Woodland period, in ceramic wares. In the seriation, no overlap was seen in point types between cultural phases. Such direct equating of point types (and, by extension, ceramic wares) with exclusive cultural phases is an example of the so-called "Coe axiom," enunciated by Brennan (1967), which holds that single point types occurred during particular cultural periods and were unique to those periods. Recent work has brought this perspective into question, indicating the contemporaneity of certain morphological types (Custer and Bachman 1986; Rue and Bergman 1991). Thus the detail and exclusivity with which Steponaitis originally attempted to refine her chronology may be unwarranted. A revised chronology published several years later did in fact acknowledge temporal overlap in several point types, although without radiocarbon dates, the Vernon and Piscataway types remained ill-defined chronologically (Steponaitis 1986).

A recent statistical analysis of the Patuxent drainage data attempted to evaluate the chronology based on the spatial distribution of each type (Reeve 1992). The analysis generally supported the Steponaitis’s outline, though there were discrepancies. For example, Piscataway was placed with Calvert and Fishtail points in the Transitional Archaic/Early Woodland, while Vernon was placed with Broadspears and Holmes in the Late Archaic (Reeve 1992:123). The association of Vernon with Late Archaic types was statistically weak. Other associations were obviously incorrect, considering accepted radiocarbon data. For example, Kirk and Palmer, firmly dated to the Early Archaic at several locales, were placed in the Late Archaic; Guilford and Jack’s Reef, radiocarbon dated to the Middle Archaic and Middle Woodland Periods respectively, was placed in the Transitional Archaic/Early Woodland. These results highlight the problems inherent with single dimensional analyses, in this instance using only spatial distribution data, assuming that types closely related in space will be closely related in time. The actual correlation between point types and temporal periods is considerably more complex than may be described by simple models.

In terms of specific correlations, the Patuxent River chronology subdivides the Late Archaic Period into five phases. The data for Late Archaic I and II indicated a great deal of overlap in the sites occupied. Botanical information from the Rowe site (McNett and Gardner n.d.), with an Archaic II component, indicated the importance of nut procurement in addition to hunting, while shellfish remains are reported at sites spanning both phases in Kent County, on the Eastern Shore of the Chesapeake (Wilke and Thompson 1977 cited in Steponaitis 1980).

The use of steatite for bowl manufacture is recognized in the Patuxent sequence in Late Archaic IV and is noted as continuing through the Fishtail Tradition. Yet the overall frequency of occurrence of the material was relatively low: the number of sites from which steatite was reported was considerably below that of sites reported with diagnostic lithics from any of the three phases. The single fragment recovered at the Kettering Park Site appeared to reflect this generally low incidence. The specimen could not be associated contextually with a specific projectile point type, and so it was arbitrarily placed in the table opposite the first occurrence of steatite in the Patuxent River chronology. Other Late Archaic points recovered at the Kettering Park Site did not appear in the Patuxent sequence. One point was identified as Lamoka, a stemmed point dated in central New York to the early portions of the Late Archaic, and three points were identified as Bare Island, a stemmed type associated with the mid-to-late portions of the Late Archaic (Ritchie 1971).

The first Early Woodland phase in the Patuxent sequence was a transitional Late Archaic/Early Woodland phase referred to as the Fishtail Tradition. This tradition was marked by Orient and Dry Brook Fishtail points and the manufacture of Marcey Creek ceramics. Steatite bowls continued in use. Lifeways during the Fishtail Tradition are believed to have been very similar to those of the preceding Late Archaic V, exhibiting a riverine focus and, in particular, taking advantage of the ongoing stabilization of estuarine environments.

The second subperiod of the Early Woodland is referred to as the Accokeek phase, defined by the presence of Accokeek Cord-Marked ceramics. A key concept in Steponaitis's evaluation of Early Woodland settlement patterns is a distinct change in lifeways between the Fishtail Tradition and the succeeding Accokeek phase, marked by a shift to a more sedentary settlement pattern. An apparent increase in the intensity of occupation at the Kettering Park Site during this period is suggested by the high frequency of occurrence of ceramic fragments. The Patuxent River artifact sample included 578 Early Woodland sherds in its entirety. The Accokeek Cord-Marked type, as employed by Steponaitis, includes all the Accokeek types discussed in this report: Accokeek Cord-Marked, Accokeek Coarseware, and Accokeek Mica-Tempered. The total of Accokeek ceramics with identifiable surface treatment from the
Kettering Park Site is 449 sherds, while an additional 150 untyped Early Woodland sherds were recovered. The combined figure of 599 was slightly greater than the number recovered for the total survey area studied by Steponaitis. Part of this discrepancy may be attributed to recovery rates in the surface collections which accounted for most of the material studied by Steponaitis, rates that may have been influenced by problems with artifact visibility and recognition. Yet the relative magnitude of site use during the Accokeek phase at the Kettering Park Site is apparent.

The associated projectile point type for this phase in the Patuxent chronology was the small, straight-stemmed Calvert type, of which only a single fragmentary example was recovered from the Kettering Park Site. The point was recovered from a mixed plowzone layer, and consequently, no definite ceramic association could be established. All of the Calvert points from the Patuxent survey were recovered from similarly mixed contexts. Yet others have been excavated from well-provenienced Accokeek contexts, as at the type site for the ceramic, Accokeek Creek (Stephenson and Ferguson 1963), and at the King I site on the Severn River (Wright 1973). One additional Early Woodland point type recovered at Kettering Park, the Potts Corner-Notched, did not appear in the collections from the Patuxent survey. The occurrence of Potts is more common in Virginia, suggesting the possibility of contacts with western populations. The high incidence of Accokeek wares and absence of Calvert points at Kettering Park may indicate that the correlation between Accokeek and Calvert is not as tight as suggested by the Patuxent data, and that other point types, such as Piscataway or Vernon, found in the same contexts at Kettering Park, were associated with the ceramics. In addition, the finding reveals the methodological problems inherent in assessing the intensity of site use for a given time period based on the occurrence of projectile points alone.

Like the Early and Middle Archaic components at Kettering Park, the Middle Woodland component was small, and of insufficient size and variety for comparative purposes. In the succeeding Late Woodland Period, site use again appeared relatively intensive. In the Patuxent River sequence, Rappahannock and Townsend are seen as indigenous complexes, while Potomac Creek and Moyaone, which occur along the Western Shore of the Chesapeake, are accepted as evidence of interaction with populations to the west. Sullivan wares were not recovered at Kettering Park, while small samples of Shepard and Riggins wares were recorded. The latter wares are characteristic of the Great Valley and Piedmont of northwestern Virginia, western Maryland and southern Pennsylvania, and of southern New Jersey, serving as additional evidence of contacts with western and, in this case, northern populations. The absence of Rappahannock series ceramics and Jack's Reef projectile points at Kettering Park suggest that extensive site use did not resume until the later portion of the Late Woodland. In contrast, the
Kettering Park Site

incidence of triangular points at the site suggests an alternative interpretation: Levanna points, which fall earlier in the sequence, occurred at greater frequency than the later Madison. As seen with the Early Woodland materials at the site, projectile point totals may not provide the most complete picture of the intensity of site use.

If the Patuxent River model were accepted as it stands, the artifactual material from the A2 horizon at the Kettering Park Site would represent seven phases of occupation and two distinct lifeways during the Late Archaic-Early Woodland transition. While multiple occupations over this period of time are a reasonable explanation for the artifactual patterning at the site, the contextual data suggest different associations between lithic and ceramic data. A key example is the temporal placement of the Piscataway type. There are no regional examples of Piscataways with firmly associated radiocarbon assays. A range of dates has been assigned to the type based on contexts of varying validity, including the Late Archaic Period, along the Potomac (McDowell 1972; Evans 1984), the Early Woodland, in southern Virginia (Mouer et al. 1981), and the Early Woodland-Middle Woodland transition in northern Virginia (Moore 1990, 1992). Many of the Piscataway points at the Kettering Park Site were recovered from the A2 horizon, in apparent association with Accokeek ceramics. If the Piscataway type were in fact indicative of Early Woodland occupation, the stratigraphic position of the points at the Kettering Park Site would be more readily explained.

The Late Woodland data from the Kettering Park Site also exhibit variation from the findings of the Patuxent River survey. However, Steponaitis (1980:34) noted an increasing degree of ceramic variability apparent during the Late Woodland, particularly in the late phase. Townsend and Potomac Creek wares were predicted to be more prevalent in the northern portion of the Patuxent Valley, but in fact the distribution of Townsend, Rappahannock, and Potomac Creek wares appeared to be fairly even throughout the drainage. The Late Woodland sample from the Kettering Park Site does to some degree conform to her expected results, with the complete absence of Rappahannock wares and the dominance of the Townsend series wares. Ceramic diversity is seen in the presence of non-indigenous wares such as Potomac Creek, Shepard, and Riggins, which, as noted, may be indicative of external contacts.

Settlement

Gardner's (1982) model for settlement patterns in the Middle Atlantic region is one of the most widely cited settlement models advanced for the area. During the Early Woodland Period on the Coastal Plain, he suggests a network of interconnected sites that form a site system. According to the model, large macro-social unit base camps were located along the shorelines
of major streams. These large camps were connected with smaller, micro-social unit camps functioning as resource procurement stations and located at seasonally determined, inland sites. A prime focus of the subsistence round was the harvesting of anadromous fish at inland stream sites in spring and early summer, and shellfish in the estuaries of high-order streams later in the season.

Gardner describes the macro-social unit base camps as "characterized by a diverse range of artifacts and a relatively large use area, and ... inhabited by a relatively large population" (Gardner 1982:56). Among the artifact assemblages indicative of these sites were comparatively high numbers of ceramics. In contrast, micro-social unit camps were inhabited by much smaller groups, and "artifacts from these locations occupy a much smaller space and are consistently made from cobble cores and core fragments, cobble core reductiondebitage, bifaces, broken projectile points (generally unfinished), and infrequent ceramics" (Gardner 1982:56). These micro-social unit camps could have been small base camps or procurement outposts, such as fishing stations.

The data from the Kettering Park Site are far from conclusive, but appeared to conform with the model on a general level. The site is situated inland, in a locale expected for a small, resource procurement camp. The artifact assemblages are characterized by evidence of expedient lithic tool manufacture. Bipolar technology at the site appeared to have been fairly extensive relative to other lithic technologies: while bipolar debitage represented only 10% of the total quartz and quartzite debitage recovered at the site, 75.8% of the cores were bipolar, suggesting that a larger proportion the debitage than was originally catalogued in fact resulted from bipolar reduction. Most of the formal tools were finished products, presumably brought to the site ready-made, while relatively few manufacturing rejects were recovered. Bifaces in general represented less than 1% of the total artifact assemblage, suggesting that ad hoc lithic tools or, perhaps, non-lithic tools were relied on heavily. The absence of features further suggests short-term site use.

The use of ceramics, and the presence of significant quantities of non-local lithic raw materials, more closely fits Gardner’s definition of a macro-social base camp. Problems with stratigraphic mixing at Kettering Park, inhibited analysis of the extent to which Early Woodland deposits at the site were the result of relatively continuous occupation or a succession of resource procurement episodes. Such a distinction is a critical factor in Gardner’s model, in which base camps were occupied on a more continuous and intensive level, while procurement camps saw more contained and episodic use.
Kettering Park Site

The data from the Kettering Park Site seem to generally conform to a model proposed by Custer (1989) for the Delmarva Peninsula. Custer (1989:142) proposes that the Late Archaic and Early Woodland Period were part of a single, overarching phase referred to as Woodland I. Woodland I is characterized by relatively sedentary lifeways in comparison with the more mobile, foraging settlement-subsistence pattern of the earlier portions of the Archaic. The peoples of this period had less portable storage technologies, larger population aggregates, and participated in elaborate exchange systems. The concept of cultural continuity between the Late Archaic and Early Woodland Periods was originally proposed by scholars such as Sears (1948) and Willey and Phillips (1958), all of whom proposed that the main difference in the lifeways of the Archaic and the Early Woodland was the addition of ceramics into the artifact inventory (Egloff 1991:248). Witthoft (1953) identified a transitional Late Archaic-Early Woodland artifact assemblage, which has become codified as the Transitional Period in some regions of the Middle Atlantic and the Northeast (Kinsey 1972; McLearen 1991). It appears that Custer's model is supported by data from the Kettering Park Site; the artifact inventory from the A2 horizon includes a relatively large variety of projectile point types that are traditionally attributed to the Late Archaic and Early Woodland and were found in apparent association with a large assemblage of Accokeek ceramics.

In terms of comparative data, few sites have been investigated in this portion of the Patuxent drainage at the resolution represented by the material from Kettering Park. The O'Barr site (18PR317), located several miles north of the Kettering Park Site on an unnamed tributary of the Patuxent, contained similar Early and Late Woodland components. Following Phase II significance testing at the site in the late 1980s, O'Barr was assessed as a small procurement camp focused on hunting. No direct evidence for fishing at the site was found. As at the O'Barr site, direct evidence of fishing was not recovered at the Kettering Park Site. No fish bone was recovered at the site, yet bone preservation in general was poor—the entire sample of bone consisted of unidentifiable fragments of avian or mammalian species. Nonetheless, based on the site location at the confluence of two tributary streams, it seems reasonable to suppose that fish represented an important resource for the Early Woodland inhabitants, and may have been a major focus of resource procurement. While no specific linkages may be proposed with the evidence at hand, the site may have served as a spring or early summer fishing camp associated with a larger base camp along the main stem of the Patuxent River.

A similar pattern of Late Archaic-Early Woodland site use was documented at the Higgins site (18AN489), on a ridge above tributaries of the Patapsco River (Ebright 1992). Echoing earlier researchers, Ebright concluded:
At an interior site on the Western Shore such as the Higgins site, Early Woodland lifeways are not expected to be appreciably different than those of the preceding Late and Terminal Archaic subperiods. Although pottery is obviously a new addition to the material culture, stone tool kits are not expected to be significantly different in terms of tool generalization or diversity, than previous Archaic tool kits. The exploitation of fish resources may again be the focus of the settlement pattern (Ebright 1992:232).

The pattern in the Late Archaic-Early Woodland transition at the Higgins site included relatively high percentages of quartz in the artifact inventory, the combined use of bipolar and freehand percussion technologies, and resource procurement focused on fresh-water fishing, particularly in the later portions of the period.

The artifact assemblage and site location of the Kettering Park Site are comparable to Late Archaic-Early Woodland transition sites in Virginia as well. Assemblages from sites of the Elk Island Tradition of the southwestern Virginia Piedmont have ceramics and lithics which are similar to those of the Kettering Park Site (Mouer et al. 1981; Mouer 1991). Similarities include the predominance of Piscataway points in the lithic assemblage, the use of friable, cord-marked pottery, and relatively high incidences of bipolar debitage. General settlement and economic patterns described for the Early Woodland Period, such as an intensive riverine focus (Klein and Klatka 1991; McLearen 1991), are consistent with the data from the Kettering Park Site.

The Late Woodland Period of the Middle Atlantic region is marked by a change to a more sedentary lifestyle and a breakdown, at the end of the Middle Woodland Period, in the exchange system that distributed rhyolite (Custer 1984). The more sedentary lifeways of the Late Woodland peoples includes an increased dependence on agriculture, and an increase in site size. However, smaller, less permanent resource procurement sites continued to be used (Gardner 1982). The apparent decrease in the quantity of rhyolite in the Late Woodland horizon at the Kettering Park Site would certainly fit this pattern. Given that the Late Woodland occupation of the site appears to be smaller than that of the Early Woodland Period, it is possible that this site functioned as a less permanent procurement area.

In terms of intra-site use, data was obtained which suggested that potential activity areas were present. Among the activity areas that could be identified were those associated with lithic production. The isolation of areas with high concentrations of discrete material types and debitage related to production stages allowed for the identification of these areas. Excavation of the site into random units, however, precludes detailed discussion of horizontal distributions.
Kettering Park Site

Lithic Raw Material Utilization and Implications for Trade and Exchange

The presence of non-local or so-called exotic lithic materials at a site indicates that the residents had access to these materials either through exchange or trips to the source of the material. As a general rule, parsimonious use of raw materials tends to be a reliable indicator of the value of that material in the economy of an occupation. Furthermore, evidence of the acquisition of non-local materials implies a knowledge of, or contact with, geographically diverse regions. The two exotic materials found in greatest quantity at the site were rhyolite and chert. The differential use of these materials may have chronological as well as economic and settlement implications.

Stewart's (1987) survey of rhyolite sources in Maryland and Pennsylvania found that rhyolite was imported from the Blue Ridge Mountains into southern Maryland and most of Virginia during the Late Archaic through Middle Woodland Periods. The general pattern in evidence in these areas is of a sharp drop in the percentage of rhyolite in lithic assemblage during the Late Woodland period, presumably a result of an increasingly sedentary lifeway (Stewart 1987). This decrease in usage is not ubiquitous, since the material continued to be important in portions of the western Maryland Piedmont through the Late Woodland Period. Sites in the inland coastal plain, such as the Kettering Park Site, are believed to follow the more generalized pattern.

Researchers in central Virginia noted a steady decrease in the use of rhyolite for projectile point manufacture: 9% of Middle Archaic points were made from exotic materials. During the Late Archaic the frequency drops to 6%, and during the Early Woodland 2% (Klein and Klatka 1991:166). The conclusion reached stated that "though exchange may have accounted for the redistribution of some raw materials, it is assumed... that the temporal patterns in lithic choice evident in the [Virginia] sample reflect trips to the source of the materials" (Klein and Klatka 1991:166). This view contrasts with that of Stewart (1987:53) who suggested that the use of rhyolite coincides with what appeared to be the first convincing evidence of trade in the Middle Atlantic. He found that most common artifacts recovered at quarry sites are those diagnostic of the Late Archaic to Middle Woodland Period. The question which remains is whether only certain groups were travelling to the source and then trading procured blanks, or whether each group was procuring its own material. As has been stated it is likely that some combination of these activities were carried out in this area.

The data from Kettering Park were difficult to interpret due to contextual mixing and the resulting lack of temporal controls on non-diagnostic artifacts. The frequency of occurrence of
rhyolite and chert debitage indicated the mixed nature of the deposits: in the A1 Horizon non-local raw materials constituted 14.9% of the total lithic material (9.8% chert and jasper, 5.1% percent rhyolite); the percentage for the A2 horizon was 8.3% (3% chert and jasper, 5.3% rhyolite). As Figure 51 indicates, rhyolite accounted for 9.9% of the bifaces at the site. Most of these were Late Archaic-Early Woodland projectile points, often small and heavily reworked. In total, 78% of these diagnostics were found buried beneath the plowzone (at level 4 N137/W101 -- a large quarry blank, and level 5 N130/W96 -- a weathered projectile point tip). Rhyolite debitage occurred in size and frequency consistent with tool refurbishing. Based on the incidence of rhyolite diagnostics, it may be that a substantial percentage of the rhyolite debitage was associated with the same Late Archaic-Early Woodland site use. The relative absence of rhyolite among Late Woodland diagnostics supports a general conformance to the accepted Middle Atlantic model of the decline in rhyolite use during the late portions of the Woodland Period.

Chert and jasper debitage was largely confined to the A1 horizon, and thus temporal associations were problematic. While this was the case, the production of Late Woodland projectile points of chert, especially a particular mustard color type, suggested that this raw material was used with some frequency during this period. Presumably much of the material was derived from external sources, probably from the nearest outcrops, in southeastern Pennsylvania. Local gravels would have provided an alternative, if not especially prolific, source. A low incidence of pebble cortex recorded in the debitage from the site suggested that, while local stream gravels were quarried for quartz pebbles, they were not an important source of crypto-crystalline material.
Assessment of Phase II Testing

The objectives of the Phase II testing program were to determine site integrity, site boundaries, cultural affiliation, and to evaluate the Kettering Park Site’s eligibility for inclusion in the National Register of Historic Places. Based on systematic shovel testing, geomorphological information, and ground conditions, the boundaries of the Kettering Park Site were well established. Phase II testing at the Kettering Park site determined the presence of relatively intact prehistoric deposits underlying the A1 horizon, which were a humus, mixed plowzone, and sheetwash deposit. The testing established the presence of the relatively intact A2 horizon, which contained Late Archaic/Early Woodland materials. Although no features were identified, the site contained abundant evidence of lithic and ceramic materials in relatively intact deposits. Included in the prehistoric assemblage was a large sample of Accokeek ceramics. For these reasons, the Kettering Park Site could contribute to the settlement and technology themes of the Maryland Comprehensive Historic Preservation Plan. In addition, the
site was considered to be eligible for listing in the National Register of Historic Places under Criterion D because it has potential to yield important prehistoric information. In particular, the site was considered an important representative of occupation of the inland Maryland Coastal Plain during the Archaic and Woodland Periods.

**Assessment of Phase III Research Goals**

The 10% sampling (13 2x2-meter units) strategy of the Phase III excavations was a viable strategy, certainly obtaining a representative sample of ceramics and lithics from the A1 horizon and the intact A2 horizon. Most notably, the excavations at the Kettering Park Site obtained the largest sample of Accokeek ceramics of any site on the Patuxent drainage. The excavations also obtained a large sample of lithics from the A2 horizon. Particularly notable in this sample was the recovery of bipolar cores.

The data obtained through the Phase III excavations identified lithic manufacturing areas. The absence of features prevented a more detailed analysis of activity areas and the ability to determine whether the ceramics were brought into the site or manufactured there; however, the presence of a large ceramic sample indicated that food preparation activities probably took place.

The use pattern of non-local or exotic materials at the Kettering Park Site indicated that its Late Archaic, Early Woodland, and Late Woodland inhabitants had access to rhyolite and chert. Given the lack of precise contextual controls for much of the rhyolite and chert artifacts, determination of the mode of artifact movement (trade or direct procurement), was difficult to establish. Based on temporal diagnostics, during the Late Archaic/Early Woodland Periods, rhyolite was the preferred material. By the Late Woodland Period, there was a decrease in rhyolite frequency, and increase in the frequency of chert use. As has been discussed, this pattern is consistent with the general patterns known for the Middle Atlantic region as a whole. The shift in material presence between these periods is thought to be indicative of both a change in lifeways (to a more sedentary settlement pattern in the Late Woodland), and in the patterns of trade (Custer 1989).

Although the ceramic sample was relatively large for the area, it was too small for the formal definition of three varieties of Accokeek ceramics (Maureen Kavanagh, pers. comm., 1993). Instead, what has been provided is the outline for defining three wares: Accokeek Cord-Marked, Accokeek Mica-Tempered, and Accokeek Coarseware. Future research at sites with a larger sample of more complete vessels may provide and opportunity to further define three
Kettering Park Site

Accokeek types. The Kettering research goals were met, thereby contributing to the Phase III research design objectives and to the settlement and technology themes of the Maryland Comprehensive Historic Preservation Plan.

Assessment of Impact and Recommendations

The location of the proposed right-of-way as indicated in Figure 3 had a direct impact on approximately 66% of the site. The Phase III mitigation obtained a statistically significant sample from the site (10%), thereby adequately mitigating the adverse affects of construction to the site. The State Highway Administration completed construction on the project.

EXPERIENCE SUMMARY

Eleven years of experience as an archaeologist in the eastern and western United States in compliance with Section 106 of the National Historic Preservation Act, as amended, and other federal, state and local legislation, as well as work in France and India. Responsibilities have included project direction, design and implementation, field and laboratory supervision, artifact analysis, archival research and report writing. Technical responsibilities include environmental and site compliance assessments, NEPA documentation of cultural resources as part of environmental assessments (EAs) and environmental impact statements (EISs), cultural resource reviews and plans, baseline surveys, and site characterizations.

EXPERIENCE RECORD

1988-Date Engineering-Science. Project Manager/Senior Archaeologist. Responsible for project management, research design, archival research, field direction, analysis and report writing in compliance with Section 106 of the National Historic Preservation Act and the National Environmental Protection Act (NEPA). He has directed projects in the United States, including urban and rural areas for private clients and public agencies. These projects have included Phase I, II and III investigations of both historic and prehistoric sites.

Representative projects include: Phase I, II and III work at the South River Colony in Anne Arundel County, Maryland; for the CNG Transmission Corporation in Loudoun, Prince William and Fauquier Counties, Virginia, and Beaver, Butler, and Armstrong Counties, Pennsylvania; the Potomac Interceptor Pipeline in Loudoun County, Virginia, and the Russett Development project in Maryland; Phase I surveys at Camp Stanley and Kelly and Lackland Air Force Bases, all in Texas; for the Maryland DOT on the Westminster Bypass; for the Transcontinental Gas Pipe Line Corporation at the M & R Station in South Carolina; Kirtland Air Force Base in New Mexico; the PEPCO Pipeline project in Montgomery County, Maryland; the Martin State Airport project in Baltimore County, Maryland; and the Baltimore-Washington International Airport in Anne Arundel County, Maryland. Phase I/II testing program for the CSX Rail Yards in Alexandria, Virginia; and Phase II surveys at Mexico Farms in Allegheny County, Maryland, and at Dulles International Airport, Fairfax and Loudoun Counties, Virginia.

1982-1987 University of New Mexico, Department of Anthropology, Albuquerque, New Mexico. Instructor, Teaching Assistant, and Research Aide.

1986 University of New Mexico, Department of Anthropology, Albuquerque, New Mexico. Field Supervisor and Researcher. Excavation of the Abri Dufaure, France, and laboratory analysis at the Musee D’Arthous, France.

1979-83 Crew Member. Projects in Nevada, New York, New Mexico, and Montana.
EDUCATION

B.A. in Anthropology (honors), Minor History, 1982, New York University, New York
M.A. in Anthropology, 1984, University of New Mexico, Albuquerque

Senior Archaeologist

EXPERIENCE SUMMARY

More than fourteen years of experience in prehistoric and historical archaeological projects in the United States, South America and the Middle East. Cultural resource projects have been conducted in compliance with Section 106 of the National Historic Preservation Act of 1966 and other federal, state and local legislation. Responsibilities have included the design, direction, organization, and implementation of large-scale archaeological projects; field and laboratory supervision, curatorial experience, artifact analysis, site interpretation, report writing and archaeological illustration.

EXPERIENCE RECORD

1993-Date Engineering-Science. Senior Archaeologist Responsibilities include the supervision and direction of historical and prehistoric archaeological projects in the eastern United States. Studies include those in compliance with Section 106 of the National Historic Preservation Act and National Environmental Protection Act, as well as state and local legislation. Currently preparing Phase III report for Kettering site, Prince Georges County, Maryland.

1990 Fulbright Scholar, Trujillo, Peru. Director of the Gallinazo Occupation of the Moche Valley Project.

1987 Yale University, New Haven, Connecticut. Director for archaeological survey of the Viru Valley, Peru.

1985 Yale University, New Haven, Connecticut. Director for archaeological survey of the Viru Valley, Peru.

1982  Proyecto Chimu Sur Project, Casma, Peru. **Staff Artist and Archaeologist.** Acted as staff artist illustrating stratigraphy, features, maps and artifacts and conducted archaeological excavation.

1980  Smithsonian Institution, Lamb Spring Project, Littleton, Colorado. **Archaeologist.** Participated in the excavation of this site.

1979  Harvard University, Peabody Museum, Mount Jasper Project, New Hampshire. **Crew Chief.** Supervised the survey and mapping of a quarry site in northern New Hampshire.

1979  Rockefeller and Israel Museums, Jerusalem, Israel. **Crew Chief.** Supervised the survey and mapping of sites in Israel.

**EDUCATION**

Ph.D., Anthropology, 1993, Yale University, New Haven, Connecticut

M.Phil., Anthropology, 1987, Yale University, New Haven, Connecticut

M.A., Anthropology, 1987, Yale University, New Haven, Connecticut

Special Graduate Student, Department of Anthropology, 1981, Harvard University, Cambridge, Massachusetts

B.F.A., 1978, Rhode Island School of Design, Providence, Rhode Island

Archaeologist

EXPERIENCE SUMMARY

Ten years of experience as an archaeologist in the Southeast, Southwest and Mid-Atlantic regions of the United States, including numerous prehistoric and historical survey (Phase I), testing (Phase II), and data recovery (Phase III) projects in compliance with Section 106 of the National Historic Preservation Act as amended for regulatory compliance with FHWA, FERC, GSA, USACOE and other federal and state agencies. Responsibilities have included project design and implementation, field and laboratory supervision, artifact analysis, archival research and report writing.

EXPERIENCE RECORD

1986-Date  Engineering-Science. Archaeologist. Served as project archaeologist, principal investigator, field director, project manager, crew chief and excavator on more than 40 archaeological Phase I, II and III projects within the northeastern and southeastern states. These projects included both historic and prehistoric sites, in urban and rural areas, including deeply buried sites along riverbanks and under twentieth-century urban fill. Responsibilities have included project design and administration, field direction and supervision, artifact analysis, historical research and report writing.

Representative projects include Phase I, II, and III investigations of historical and prehistoric sites along a 56-mile natural gas transmission line corridor in western Pennsylvania; Phase I, II, and III investigations of prehistoric sites along a 30-mile natural gas transmission line in northern Virginia; Phase III maritime data recovery at Keith's Wharf, Alexandria, Virginia; Phase III study of Lanes Mill, Fairfax County, Virginia; Phase I and II surveys of prehistoric sites at proposed federal courthouse site in Prince Georges County, Maryland; Phase III excavations at the prehistoric and historical sites of the new correctional treatment facility in Washington, D.C.

1985  Virginia Research Center for Archaeology/Mt. Vernon. Field Crew/Laboratory Analyst. Data recovery excavations within the North Grove/Blacksmith's Shop at Mt. Vernon.

1983  University of Texas at San Antonio Colha Project/Northern Belize Crew Chief. Mayan lithic tool production site; assisted in directing excavations within two separate ceremonial centers.

1982  University of Texas at San Antonio Field Crew and Lab Analyst. CAR Blue Bayou Project -- late prehistoric burial site, South Texas; CAR East Chacon/Exxon Survey, prehistoric site survey of 30,000-acre tract, South Texas; CAR Brooks County/Chevron Survey, Phase I prehistoric site survey, South Texas.

University of Texas at San Antonio/CAR Fort Sam Houston Cemetery Survey -- Field Crew. Phase I backhoe testing. Center for Archaeological Research Guenther's Mill Project --Field Crew Phase III mitigation and conservation of mill race on San Antonio River.

1981  University of Texas at San Antonio Field School. Field School Student. Phase III excavations at Late Prehistoric occupation site within Choke Canyon Reservoir, South Texas.

SITE DESCRIPTION

The Kettering site is located on a low alluvial terrace, about 60 x 80 m, on the south side of Maryland Rte. 214 between Largo and Kolbes Corner (Figure 1). The site, at the confluence of the Western and Northeastern Branches of the Patuxent river, is underlain by Quaternary fluvial sands and gravels of the Wicomico Formation (Cooke and Cloos, 1951). The surrounding coastal plain uplands are underlain largely by the Tertiary Aguaia greensand (a green glauconitic sand) and by less extensive outcrops of the Tertiary Chesapeake group (light grey diatomaceous earth and fine pebble sand) (Cooke and Cloos, 1951). Soils developed on the uplands are mapped as Collington fine sandy loams (Kirby et al., 1967). Stream gradients are gentle and relief is subdued. The site was once farmed, reforested, and recently partially cleared to leave an open, park-like stand of trees, primarily Beech, of typically 25-30 cm diameter.
PARENT MATERIAL

The parent material upon which soil has formed consists primarily of well sorted fine and medium sand, with lesser occurrences of gravely sand, sandy gravel, and silty sand. The deposits are interpreted as fluvial deposits of the Western and Northeastern Branches, and possibly of a small tributary that drained the upland to the north and once joined the Northeastern Branch near the eastern margin of the site. A road now occupies this draw, so it is difficult to reconstruct the paleodrainage to assess the possible contribution of sediment from this stream to the alluvium at the site.

Changes in parent material size are believed to be responsible for the sharp contacts observed in some profiles (from sand to gravel, and from sand to silty sand). However, most soil development has occurred on a massive fine-medium well-sorted sand that extends to depths of 1 m in most profiles. This sand lacks evidence of primary sedimentary structure or textural change. Fine sands deposited in the backwaters of major floods could be responsible for a massive primary depositional structure. Conceivably, the sand could have been deposited as one event. Alternately, sequential events could be responsible, with all primary stratification since lost to soil development.

Stratigraphic relations below the sand are complex. Gravels suggest that paleochannels (former channels) crisscrossed the site, but more deep holes would be required to map these former
channels. A more recent gravel occurs at a depth of 40 cm in auger hole N80 W100. A fresh-looking fragment of glass was found here at a depth of 70 cm; it was dated as post 1923 on the basis of its lettering (a portion of "reuse of this bottle is prohibited ...") and probably post 1950 on the basis of the quality of glass (Silas Hurry, pers. comm.). This gravel is overlain by 40 cm of thickened A horizon and appears to have been inset into the sloping terrace edge by a recent flood (see Plate 1). Other gravels underlie the primary sandy unit and thus predate the sand and its pedogenesis.
PROCEDURE

To obtain the most usable information most efficiently, existing archeological pits were described and soil profile descriptions logged from shovel test pits (s.t.p.'s) on a 5m grid were adapted for use in stratigraphic cross sections. One line of auger holes was drilled along the W100 transect. In order to use the auger hole and s.t.p. data, 4 transects were levelled, two N-S (W100 and W115) and two E-W (N101 and N121). Locations of auger holes, s.t.p.'s, and soil pits used in this analysis are shown on Figure 2. Although s.t.p.'s are shallow and thus do not yield data on underlying stratigraphy, they are important for determining the lateral extent of soil units.

Soils were described in the field for color, texture, and consistency. Given the scope of the project, no size analyses or other laboratory tests were performed.

Textural descriptions recorded by Cavanaugh were adjusted to reflect the higher sand fractions observed in nearby holes; these adjusted textures are used in Plates 1-4.
PEDOGENIC DEVELOPMENT

The soil at the site is mapped as Bibb Silt-loam in the Prince Georges County Soil Survey (Figure 3; Kirby et al, 1967). The description of this unit includes mention that, "In a few areas the surface layer contains medium sized sand and feels gritty" (Kirby et al, 1967, p. 19). The Kettering site is such an area. The soils here are loamy sands and sandy loams. In most pits a cambic B and argillic B are developed. Parent material usually changes at the base of the B horizon.

Colors are quite red in the argillic B horizons, although color can vary dramatically from pit to pit. For example, pit N115 W105 is only a few meters from pit N118 W110, yet it is strikingly redder. Occasional thin clay skins are visible in the argillic B. Structure is generally weak to moderate in A, cambic B and argillic B horizons. Sands and gravels that underly or overly the soil may be massive and structureless.

A representative profile N118 W110 is shown in Figure 4. Recall that there is substantial variation from hole to hole, especially below about 80 cm depth.

Mottles are common below 80 cm depth, indicating that this site is poorly drained. Iron oxide cemented concretions (usually 80-100 cm) reflect the abundance of iron available from the weathering of the glauconite derived from the greensands of the uplands deposited at the site.
AGE AND STABILITY OF SOIL

Aside from the recently inset gravel (N80 W100), and the possibly recent deposition of sand over a now buried B horizon at N130 W75, the site appears to have been stable long enough that an argillic B horizon could develop. How long is that? To answer this question, we can refer to studies by other workers who have used independent means (such as C-14 isotopes) to date soils of varying stages of development. We must bear in mind, however, the rates of soil formation are influenced by climate, microclimate, drainage, parent material size and minerology, vegetation, and erosional or depositional modifications after onset of pedogenesis.

Many studies of soil formation rates are reviewed by Hall et al (in press). Table 1, taken from their report, indicates that translocation of clay can occur in as little as 100 years or less (Hallberg et al, 1978). More comparable are the data of Bilzi and Ciołkosz (1977), indicating that illuvial clay is found after 2000 years of development on alluvium in the Pennsylvania Appalacians. Taken as a whole, these studies suggest that about 2000 years minimum are needed to develop an argillic B horizon.

At the Kettering site, the parent material is extremely sandy. This would serve to accelerate pedogenesis because the surface area to be weathered is less than in a finer grained parent material. However, the site's low topographic position and consequent poor
drainage would serve to slow pedogenesis by preventing optimal aeration.

The combination of red color and argillic B development suggest an age of 10,000 years B.P. ± 4,000 (Jacobson, pers. comm., 1983) for the main body of the site.
EROSION OF THE SITE

Pronounced thinning and thickening of the A horizon is apparent in Plate 1. Several factors may have contributed to this phenomenon: erosion of the surface by sheet wash, trapping of sediment by tree roots, disturbance by plowing, and disturbance by heavy equipment.

Plow scars indicate that the site was once farmed, but it is now forested, primarily by Beech trees 25-30 cm in diameter.

A cut stump of unknown species (not Beech) and about 30 cm in diameter is located near the highway. Its 120 annual rings suggest that the present stand is well over a century in age. Some trees in the North-central and eastern part of the site are on mounds about 20 cm above the surrounding ground surface (see Plate 2). Roots are fully or partially exposed on the mounds. It is unclear whether these mounds indicate lowering of the surrounding surface by erosion or raising of the mound by 1) accumulation of soil at the base of the tree or by 2) growth of tree roots and heaving the soil. Mounds are found not only under Beeches, but under other trees as well. If the Beech mound located at N131 W100 (Plate 1) is representative, the thickening is restricted to the A horizon, suggesting either erosion of the surrounding surface or trapping soil at the tree base, not heaving.

Only 12 km east of the District of Columbia, the site is in an area that has undergone rapid urbanization over the past 25 years.
Early 1960s aerial photography of the site (for SCS) shows the site and the adjacent floodplains of the Western and Northeastern Branches of the Patuxent were heavily forested. When the Kettering development was constructed, much of the floodplain was cleared of trees. On the alluvial terrace at the site, trees were thinned and the underbrush cleared out (Richard Naegle, surveyor, pers. comm., 11 May 1983). A park now exists on the site. The heavy equipment used in creation of the park and removal of trees probably disturbed upper soil horizons.
EROSION OF SITE EDGE

The edge of the stable surface at the site is determined primarily by 1) road construction (on the north edge) and 2) fluvial erosion by the Northeast Branch (SE edge) and by the Western Branch (W edge). Paleocourses of the two streams are shown in Figure 1. They are taken from the Lanham 7.5' Quadrangle, photorevised in 1979(?). It is clear that these channels formerly abutted the edges of the site. The old mill over the Western Branch and its mill pond (Figure 1) do not appear on aerial photography from the early 1960s (photo base for Kirby et al, 1967) and are reported to have been put there as part of the landscaping for the Kettering development (Richard Naegele, surveyor, pers. comm.). Thus, it appears that the present channels are artificial and that prior to development, the streams flowed along the edge of the site, where they could be expected to erode and deposit during high flows.

Pits, auger holes, and s.t.p. descriptions were examined for holes at the edges of the site. By correlating the described and dated gravel in hole N80 W100 with gravel and sand in s.t.p. descriptions, the extent of inset fluvial gravel and sand is reconstructed in Figure 2, depicted by the solid line. The correlation is uncertain since the gravels and sands in the s.t.p.'s and described by Cavanaugh (unpubl. data) were not observed by the author. If this correlation is correct, the landward edge of the inset gravel represents the edge of erosion
of the site. If the gravels described in s.t.p.'s are not modern and thus not correlative, then the edge of erosion of the site is farther south, depicted by the dashed line in Figure 2.
SUMMARY AND CONCLUSIONS

The Kettering site, located on a low alluvial terrace, is underlain primarily by fine-medium well sorted fluvial sands, derived from greensand outcrops of the uplands. Occasional gravels underlie and predate the principal sandy unit, and modern gravels are inset along the Southeast margin of the site, suggesting erosion of the bank and emplacement of a point bar by high flows on the Northeast Branch. A fresh fragment of glass (probably ca. 1950s or later) found in the gravel indicates that the event was recent.

Most pits show development of an argillic B horizon, with occasional thin clay skins and weak-moderate structure. The redness of these soils and the presence of an argillic horizon suggests a minimum age of 2000 years B.P., more probably 10,000 years B.P. ± 4000 years.

As mentioned above the Southeast edge of the site has been eroded by the Northeast Branch. The A horizon of the site has been disturbed by plowing, heavy equipment, and possible sheetwash erosion or colluvial movement.

APPENDIX C

ARTIFACT INVENTORY CODES

Inventory Format

The artifact inventories which follow are presented in column form. The first inventory lists the provenience and a description of each artifact recovered in the three phases of investigation. The following inventories list detailed measurements and descriptions of the ceramics, bifaces, ground/use-modified artifacts, cores and unifaces respectively.

Database Codes

Most of the inventory entries consist of words which are self-explanatory. Other entries were too lengthy to fit into the fields of the inventory format, and have been abbreviated. Explanations of the abbreviations follow.

Abbreviated Headings:

Appendix J
Maryland Archeological Site Survey Form (Updated)
MARYLAND ARCHEOLOGICAL SITE SURVEY: BASIC DATA FORM

Maryland Department of Natural Resources
Division of Archeology

Maryland Geological Survey
2300 St. Paul Street
Baltimore, Maryland 21218

Site Number 18 PR174

Shaded areas are for Division of Archeology use only

A. Designation

1. County: Prince Georges

2. Site Number: PR174

3. Site Name: Kettering Park

4. Site Type (check all applicable):
   - x Prehistoric
   - ___ Historic
   - ___ Unknown

5. Maryland Archeological Research Unit Number: 8

B. Location

6. USGS 7.5’ Quadrangle(s):
   Lanham 1971
   (Photocopy section of quad(s) on page 4 and mark site location)

7. UTM Coordinates at Center of Site
   Zone: __________

8. Easting: __________

9. Northing: __________

10. Physiographic Province (check one):
    - _____ Allegheny Plateau
    - _____ Ridge and Valley
    - _____ Great Valley
    - _____ Blue Ridge
    - _____ Lancaster/Frederick Lowland
    - _____ Eastern Piedmont
    - x Western Shore Coastal Plain
    - _____ Eastern Shore Coastal Plain

11. Nearest Water Source:
    Western and Northern Branches

12. 2nd Nearest Water Source: __________________________

13. 3rd Nearest Water Source: __________________________

14. 4th Nearest Water Source: __________________________
C. Environmental Data

15. Closest Surface Water Type (check all applicable):
   - Ocean
   - Estuarine Bay/Tidal River
   - Tidal or Marsh
   - Freshwater Stream/River
   - Freshwater Swamp
   - Lake or Pond
   - Spring

16. Distance from closest surface water: 0 meters (or 0 feet)

18. Topographic Settings (check all applicable):
   - Floodplain
   - Interior Flat
   - Terrace
   - Low Terrace
   - High Terrace
   - Hilltop/Bluff
   - Upland Flat
   - Ridgetop
   - Rockshelter/Cave
   - Unknown
   - Other:

9. Slope:

20. Elevation: 0 meters (or 0 feet) above sea level

21. Land use at site when last field checked:
   (check all applicable)
   - X Plowed/Tilled
   - No-Till
   - Woodyed/Forest
   - Logging/Logged
   - Underbrush/Overgrown
   - Pasture
   - Cemetery
   - Commercial
   - Educational
   - Extractive
   - Military
   - Recreational
   - Residential
   - Ruin
   - Standing Structure
   - Transportation
   - Unknown
   - Other:

22. Condition of Site (check all applicable):
   - UNDISTURBED
   - DISTURBED
   - Plowed
   - Eroded
   - Graded/Contoured
   - Collected
   - Vandalized
   - Dredged
   - Other:

   DESTROYED
   - X minor (0-10%)
   - moderate (10-60%)
   - major (60-99%)
   - total (100%)
   - % unknown

23. Additional Comments on Environment:
24. Site Type A (check all applicable):

PREHISTORIC
- Lithics
- Ceramics
- Shell Midden
- Unknown
- Other:

HISTORIC
- Cemetery
- Domestic:
- Urban
- Rural
- Educational
- Industrial:
- Urban
- Rural
- Military
- Religious
- Water Transportation
- Unknown
- Other:

- UNKNOWN

25. Site Type B (check one):
- Terrestrial
- Underwater
- Both

26. Cultural Affiliation (check all applicable):

PREHISTORIC
- Unknown
- Paleoindian
- Archaic
- Early Archaic
- Middle Archaic
- Late Archaic
- Woodland
- Early Woodland
- Middle Woodland
- Late Woodland
- CONTACT

HISTORIC
- Unknown
- 17th century 1630-1675
- 1675-1720
- 18th century 1720-1780
- 1780-1820
- 19th century 1820-1860
- 1860-1900
- 20th century 1900-1930
- post 1930

- UNKNOWN

27. State Plan Themes:

28. Site length: _____ meters (or _____ feet)
29. Site width: _____ meters (or _____ feet)
30. Is site confined to plowzone?
   - Yes
   - No
   - Unknown
31. Does site have subsurface integrity?
   - Yes
   - No
   - Unknown
BASIC DATA FORM

Photocopy section of quadrangle map(s) and mark site location with heavy dot or circle and arrow.

E. Support Data (Use additional sheets if needed)

32. Accompanying Data Form(s):

- Prehistoric
- Historic
- Submerged
- Shipwreck

33. Ownership:

- Private
- Public
- Unknown

34. Owner:  Carrollton Realty, 11620 West Branch Drive, Kettering, Upper Marlboro

Address:  1160 West Branch Drive Kettering Upper Marlboro, MD 20870

Phone:  (301) 249-9553

Date:  7/26/79

35. Tenant:

Address:  

Phone:  

Date:  

36. Known Investigations:

- Phase I Survey
- Phase II Testing Maureen Kavanagh, Silas Hurry Directors
- Phase III Excavation Maureen Kavanagh, Silas Hurry Directors

37. Reports

(Author & year):

- Terrence Epperson 1979
- Heidy Fogel and Dennis Knepper 1993

38. Other Records?

- Yes
- No
- Unknown

39. If YES, type and location:

- All Fieldnotes, Photographs, dBase III+ files will be deposited at the Maryland Historic Trust

40. Collections?

- Yes
- No
- Unknown

41. If YES, give owner and location:

- All artifact will be curated at the the Maryland Historic Trust Facilities

42. Artifact Conservation?

- Yes
- Partial
- No
- Unknown
43. Maryland Register Status:
   - Listed on register
   - Nomination pending
   - x Determined eligible (formal)
   - Considered eligible (consensus)
   - Not eligible
   - Insufficient data

44. National Register Status:
   - Listed on register
   - Nomination pending
   - x Determined eligible (formal)
   - Considered eligible (consensus)
   - Not eligible
   - Insufficient data

45. Informant:
   Address: 
   Phone: 
   Date: 

46. Site visited by:
   Address: 
   Phone: 
   Date: 

47. Form filled out by: Heidi Fogel
   Address: 1133 15th Street N.W. Suite 700 Washington D.C.
   Phone: (202) 775-3495
   Date: Nov. 3, 199

53. Date: 

54. Form updated by: 

55. Date: 

1. Site type (check all applicable):
   
   ___ village
   ___ hamlet
   ___ base camp
   ___ short-term resource procurement
   ___ lithic quarry/extraction
   ___ rock shelter/cave
   ___ cairn
   ___ earthen mound
   ___ shell midden
   ___ fish weir
   ___ submerged prehistoric
   ___ lithic scatter
   ___ unknown
   ___ other:

2. Categories of aboriginal material or remains present at site (check all applicable):
   ___ flaked stone
   ___ ground stone
   ___ stone bowls
   ___ fire-cracked rock
   ___ other lithics
   ___ ceramics (vessels)
   ___ other fired clay
   ___ faunal skeletal remains
   ___ faunal implements/ornaments
   ___ faunal material
   ___ oyster shell
   ___ floral material
   ___ unknown
   ___ other:

3. Lithic materials (check all applicable):
   ___ jasper
   ___ chert
   ___ rhyolite
   ___ quartz
   ___ quartzite
   ___ chalcedony
   ___ ironstone
   ___ argillite
   ___ steatite
   ___ sandstone
   ___ silicified sandstone
   ___ ferruginous quartzite
   ___ European flint
   ___ basalt
   ___ unknown
   ___ other:

4. Diagnostics (choose from manual and give number recovered or observed):
   ___ 8 Piscataways
   ___ 4 Vernons
   ___ 1 Madison
   ___ 8 Levannas
   ___ 1 Potts Corner-Notched
   ___ 1 Calvert
   ___ 2 Susquehanna Broadspears
   ___ 1 Drybrook Fishtail
   ___ 1 Orient Fishtail

5. Features present:
   ___ yes
   ___ no
   ___ unknown

6. Types of features identified (check all applicable):
   ___ midden
   ___ postmolds
   ___ house patterns
   ___ palisade
   ___ hearths
   ___ chipping clusters
   ___ refuse/storage pits
   ___ burials
   ___ ossuaries
   ___ unknown
   ___ other:
7. Method of sampling (check all applicable):
   - x non-systematic surface search
   - x systematic surface collection
   - x non-systematic shovel test pits
   - x systematic shovel test pits
   - x excavation units
   - x mechanical excavation
   - x other:
     extent/nature of excavation:

8. Flotation samples collected:
   - yes
   - no
   - x unknown
   analyzed:
   - yes, by ______________
   - no
   - unknown

9. Samples for radiocarbon dating collected:
   - yes
   - no
   - x unknown
   Dates and Lab Reference Nos. __________

10. Soil samples collected:
    - x yes
    - no
    - unknown
    analyzed:
    - yes, by ______________
    - no
    - unknown

11. Other analyses (specify): Blood Residue

12. Additional comments:
    Additional Diagnostics 2 Brewerton Ear-Notched, 3 Bare Islands, 3 Normanskills, 449 Accokeek Sherds, 2 Marcey Creek sherds, 3 Selden Island sherds, 10 Mockley Sherds, 53 Townsend Sherds, 6 Moyaone Sherds, 1 Potomac Creek Sherd, 1 Shepard Ware Sherd, 16 Riggins Ware sherds
